be registered as a medical or dental student who has not attained the age of 16 years; and for the purpose of ensuring the observance of this regulation every applicant for registration in the Students Registers shall be required to produce satisfactory evidence that this age has been attained.

Sir JOHN BATTY TUKE, seconded by Dr. MACALISTER, moved the adoption of the second recommendation.

Mr. HORSLEY wished to know if the existing list of examinations was to be absolutely abrogated if the committee were authorised to carry the new scheme into effect. He could not see how the scheme was to be carried out without considerable expense, for after two years' time he took it that the Council would have to employ the experts as inspectors. He took it that the Council had full confidence in the committee to carry out the scheme. The recommendations of the experts fell short, he thought, of what they might expect. They were governed by serious limitations in the narrative which went to show that the experts themselves felt that there were great difficulties in making the recommendations and that there would be difficulties in carrying them out. He was sent to the Council to speak in favour of a much higher examination and he should always do so. But if the Education Committee said, "Have confidence in us and let us try this scheme for two years or so," he could not very well see how the Council could refuse.

Dr. PAYNE pointed out that, broadly speaking, the higher class school life of this country did not end till the pupils were 18 years and he wished their intending medical students could remain at school until that age. In Germany and France the age for intending medical students leaving school was from 18 to 19, and in his view the standard of general education for the medical profession was consequently higher than in this country. If, however, they made the "senior" examination the necessary standard they would not be fixing an educational standard but a social and financial standard. They would be laying down the opinion that intending medical students should be able to afford school till the age of 18 years. He really doubted if that would be possible generally. There was an average of quite two years' difference between the "junior" and the "senior" examinations. With a five years' medical curriculum it would be difficult to go beyond 16 years as the minimum age limit, and that was another difficulty in the way of making pupils looking forward to enter upon medical studies stay at school until 18 years of age. If the scheme now put forward were adopted he was sure that Oxford and Cambridge would do what they could to meet the views of the Council. But the Council would hardly expect them to alter their whole scheme of examination to do that. At one time he was of the opinion that all the Council needed to do to secure the raising of the standard was to pass a resolution abolishing all the junior examinations, but he had come to the conclusion that the amount of reform now offered was the utmost which at the present moment could be satisfactorily carried out.

Dr. MACALISTER believed that he was expressing the feeling of the Education Committee when he said they were gratified that their labours, which had not been light, had been so well received by the Council. With regard to the expense in giving effect to the scheme the Council at the last meeting had made a grant of £100 in connexion with the work of the experts, and the committee hoped that a great deal more could be done without more money. What remained of the £100 was practically sufficient for at any rate the preliminary work. There was nothing secret or mysterious about the confidential documents or anything to be ashamed of. Those who furnished them desired that the details of their examinations should not be made public in any way simply because they would get to the ears of students and teachers who would prepare up to a certain standard and no higher. The committee and experts would be breaking faith if they made the documents public.

Dr. MCVAIL called attention to the fact that in one part of their joint report the experts expressed this conclusion: "Such examinations are comparatively worthless as tests or a good preliminary education." He asked if there were many and recognised examinations to which that could be applied.

Dr. MACALISTER explained that there were only one or two, and even in connexion with these the conclusion was explainable. It referred to languages only; that books should not be prescribed. It was solely with reference to the question of set books or not set books. It did not speak of examinations as a whole. As to the experts' series of recommendations it would be of no use considering these one by one. They must be taken as a whole or left altogether alone. It would not do to take some and leave others.

Sir CHRISTOPHER NIXON had no doubt that quite a number of bodies would not accept the experts' recommendations, but if the Council could secure the fixing of a minimun standard of examination below which they would not allow a youth to be registered as a medical student, and do that without any revolutionary measures, it would be a decided gain, and for that reason he strongly urged the Council to pass these recommendations.

Dr. MCVAIL had hoped they would have got more than the committee and the experts offered, and he thought that the Council, while agreeing to what was presented, might indicate that the time would come very shortly when they would demand a much higher standard. The committee should at once set to work to furnish a list of the bodies with whose examinations the Council could be entirely satisfied. The present list was not quite reliable because it took men from anywhere and everywhere.

The motion proposed by Sir JOHN BATTY TUKE was agreed to. Accordingly, the Education Committee were authorised by the Council to take all needful steps to give effect to the recommendations and suggestions for the improvement of preliminary examinations contained in the joint report of the expert advisers and to report from time to time to the Council thereupon.

Sir JOHN BATTY TUKE moved a vote of thanks to Mr. Sharpe, Dr. McGrath, and Professor McCormick for the valuable assistance which they had given to the Council in relation to the question of preliminary examinations.

Dr. MACALISTER seconded the motion.

The PRESIDENT said that having had the opportunity of knowing perfectly the great labours that these gentlemen had given to the consideration of the matter in question, and also knowing what fee was placed at the disposal of the Education Committee, he should like to say that these gentlemen had done a great deal more work than they had been paid for in money, therefore he thought the Council should record their thanks for the work they had done.

Dr. LITTLE asked if it was becoming on the General Medical Council to employ three experts and not pay them properly. He would rather propose that they should receive an addition to their honorarium. He did not know them at all.

The PRESIDENT said that these gentlemen undertook the duty, not in view of a money payment, but rather from a desire to help the Council in this branch of their work.

The motion was agreed to.

The Pharmacopœia.

Dr. MACALISTER, deputy chairman, in the absence of Dr. Leech owing to illness, presented the following report by the Pharmacopœia Committee:—

The Pharmacopœia Committee desire to record their regret at the enforced absence through illness of their chairman, Dr. Leech, and their grateful acknowledgments of the manner in which he has carried on the work of the committee since their last meeting.

The committee have now to report that 31,500 copies of the British Pharmacopœia of 1898 have been printed, and 28,783 of these have passed into circulation, leaving in hand 2717 copies.

A communication from the Privy Council, forwarding a copy of a note addressed to the Secretary of State for Foreign Affairs by the Belgian Minister, on the subject of a proposed International Pharmacopœia limited to drugs of a drastic nature, has been referred to this committee by the Executive Committee. The committee recommend the Council to reply that, should an international conference on the subject in question be arranged, the Council would be prepared to appoint representatives to participate in it and to authorise the President to appoint one or more members to act as delegates.

Another meeting of the conference of members of the Pharmacopœia Committee with representatives of the Pharmaceutical Society of Great Britain and the Pharmaceutical Society of Ireland has been held, and on its recommendation certain questions of a pharmacological and pharmaceutical nature have been referred to experts for further investigation and report.

Communications have been opened with the United States authorities with a view to bringing about greater uniformity in the official preparations contained in the British Pharmacopœia and the United States Pharmacopœia respectively, and it is hoped that, by mutual concessions, important approximations and assimilations in the contents of the two works may be ultimately secured.

Further communications have been received with reference to the Indian and Colonial addendum and important suggestions from Canada have been considered by the committee in detail. A report on progress has been prepared by the editor and is hereto annexed. It is hoped that a final draft of the addendum may be presented to the Council at the November meeting and that the addendum itself may be authorised for issue by the end of the year.

By the assiduous efforts of Dr. Leech a valuable collection of British

and foreign works bearing on the history and development of the pharmacopœia has been got together and deposited in the Council's office. Thanks are due to Dr. Leech, Mr. Bryant, Mr. Ekin, and Mr. Walter Hills for important contributions to this collection, and the committee hope that from time to time further additions may be made to it by members of the Council and others. A hand list of the works already deposited has been printed and will be sent to members of the Council, and a card catalogue prepared under Dr. Leech's direction is placed with the collection in the committee room.

On the motion of Dr. MACALISTER, seconded by Dr. LOMBE ATTHILL, this report was received, entered on the minutes, and adopted, and the Council recorded cordial thanks to Dr. Leech, Mr. Bryant, Mr. Ekin, and Mr. Walter Hills for the important contributions they had secured for the Pharmacopœia Library.

The Council adjourned.

THURSDAY, MAY 31ST.

The Council met again to-day, Sir WILLIAM TURNER being in the chair.

The Council and the English Royal Colleges.

On the motion of Dr. MACALISTER the following report was received and entered on the minutes, viz.:—

REPORT BY THE EDUCATION COMMITTEE ON CERTAIN COMMUNICATIONS FROM THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The Education Committee have given careful and prolonged consideration to the communications forwarded by the Royal College of Physicians of London and the Royal College of Surgeons of England with reference to the new regulation for the registration of medical students, which communications have been laid before the Committee by direction of the President.

This regulation was adopted by the Council on June 7th, 1899, on the recommendation of the Education Committee, who reported as follows (Minutes, vol. xxxvi., p. 562):—

"The licensing bodies should be informed that schools for boys and girls were not intended by the Council to be regarded as institutions at which the first of the five years of medical study may be spent, and the Council should require that before registration is effected a student should have commenced medical study at a university or school of medicine or at a scientific institution recognised by one of the licensing bodies and approved by the Council. If this were done the recognised institutions would not merely as now be reported to the Registrar but would come in a regular and formal way before the Council for its approval. Attention could thus be drawn to any institution regarding which objection might be taken and approval withheld if the evidence as to its status and efficiency were unsatisfactory. As registration is a matter over which the Council alone has control this manner of dealing with the difficulty appears to be the least open to objection."

The regulation, which came into force on Jan. 1st, 1900, read as follows:—

"No medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council and has commenced medical study at a university or school of medicine or at a scientific institution recognised by one of the licensing bodies and approved by the Council."

The Royal College of Physicians of London and the Royal College of Surgeons of England, alone of all the licensing bodies, have taken objection to this regulation, and on Oct. 26th and Nov. 2nd, 1899, they adopted a resolution affirming that they "fail to recognise any authority under the Medical Acts in virtue of which the General Medical Council may impose the conditions formulated in the regulation in regard to the registration of medical students," and that "they decline to recognise the requirement that scientific institutions where medical study is commenced should be approved by the General Medical Council."

This intimation was conveyed to the Council on Dec. 4th, 1899, when the President was requested to inform the Royal Colleges that the Council adhered to its regulation and to invite the Colleges to take the matter into fresh consideration in view of its important bearing on the maintenance of the standard of study and examinations in the country at large.

The President informs the committee that he has had an opportunity of conferring with representatives of the Royal Colleges on the subject and that the Committee of Management of their Examining Board submitted a report upon it to the two Colleges. The Committee of Management stated that "after a full consideration of the question in all its details they are unable to discover any grounds for altering the decision of the Royal Colleges" as stated in the resolution above referred to. They also appended a memorandum, copies of which have been courteously furnished to the Education Committee, setting forth the legal and other grounds for the view they had taken. The report of the Committee of Management has now been adopted by the Royal Colleges and constitutes their answer to the Council.

Three questions appear to arise for the consideration of the Council:—

1. Whether it is in the interest of medical education generally that the first year of medical study should be taken at ordinary schools of higher elementary or of secondary education, even when these give good elementary instruction in science in addition to the other subjects of school study?

2. Whether it is contrary to law or beyond the powers of the Council to impose the conditions formulated in the regulations under which a student may be registered as having passed a suitable preliminary examination and as having entered on a course of medical study?

3. Whether any one of the licensing bodies can legally require the General Medical Council to enter on the register of medical students the name of a student who has not fulfilled the conditions prescribed by the Council itself?

I.—On the first question the committee maintain the opinion they have repeatedly expressed that ordinary school education should be completed before the five years' medical curriculum is entered upon, and they believe that the regulation in question is the simplest practical method of insuring this. They therefore recommend that the Council should continue to adhere to it.

II.—On the second and third questions the committee recommend that the opinion of the Council's legal adviser be obtained before the next session of the Council.

III.—With regard to the individual applications for registration which have been received by the Registrar since Jan. 1st, and which cannot be dealt with by him without further instruction, the committee recommend that they be referred to the Students' Registration Committee as exceptional cases to be dealt with on their individual merits.

Dr. MACALISTER, in moving the adoption of the first recommendation of the committee, said that 12 copies of a memorandum prepared by the Royal Colleges had been received. They were marked "Confidential" and they would be circulated among the members of the Council so far as they would go. He understood that the memorandum had been prepared for the information of the Colleges. Reference was made to a legal opinion obtained by the Colleges, but the legal opinion was not given, and therefore as a member of this Council he could not state what line it took.

Mr. HORSLEY asked whether it would not be well to defer this motion until next session in order that members might have an opportunity of studying the memorandum.

The PRESIDENT said there was no reason why Mr. Horsley should not have a copy of the memorandum given to him now.

Mr. HORSLEY declined to vote upon the question before he had had an adequate opportunity of studying the memorandum.

Dr. MACALISTER, after explaining that it was only yesterday he obtained permission to circulate the memorandum, said that practically the memorandum decided the question which had to be discussed by the Council. The Royal Colleges had taken up the position apparently that the Council had no legal right to lay down such conditions as they had laid down for the registration of medical students. By doing so they confused the issue. The registration of students was a matter for this Council. With regard to the actual course of study which a student must have gone through for the diploma of the licensing bodies, that was a matter under their supervision, but they had no legal power to define beforehand or to control in the sense in which the word was used by the Royal Colleges. If they (the Council) were dissatisfied with the actual course of study which the licensing bodies had prescribed and required they could represent the matter to the Privy Council, and that was the limit of their control over the actual course of study pursued by any of the licensing bodies. He asked the Council to distinguish clearly between the two things—the registration of students and the course of study. The whole argument of the Royal Colleges was addressed to the second of these, and the Council had to address itself to the first. The Council asked of students that they should have passed a preliminary examination which they thought was sufficient and that they should have *bonâ-fide* commenced the five years' course of medical study. The Royal Colleges practically failed to recognise the right or authority of the Council to require either of these things. The Students Register had been established by the Council for their information, that they might have a means of testing first of all how long the curriculum of students was and secondly of ensuring that they had had a sufficient preliminary training before they began their medical studies. The question was what was five years of medical study from the point of view of this Council. They had pointed out that if students were allowed to pass six months of their period of medical study in higher elementary schools they were to this extent diminishing the medical curriculum; the Council had long protested against what might be called half-timers in respect of medical study. The Students Register was the creation of this Council, and he for one held that they had a right to state what were the conditions for entering a man's name upon it. If the Council still took the view that medical half-timers were not to be admitted to the Students Register then they must adhere to the conditions they had laid down—it was the only way to stop the growth of the practice. The Council did not dictate what conditions the Colleges should accept, but they said what conditions they (the Council) should accept. All the bodies except the two Royal Colleges in England had accepted the

regulations of the Council as they stood. Many of them declined to recognise this elementary or public school medical education at all. They protested very strongly against it being recognised by this Council and he thought they had a right so to protest. Yet if the Council accepted the suggestion of the Royal Colleges and put everyone on the Register whom they desired to be put on the other bodies would be so far coerced and controlled. The Royal Colleges therefore asked not only to control the Council but also to control all the other licensing authorities. That was a position which he thought the Council ought strenuously to resist. The Students Register was not a statutory obligation upon the Council. It was a creation of the Council—a piece of mechanism for carrying out the purposes of the Act. It was not statutory but it was not *ultra vires* and it was not illegal.

Dr. PAYNE, seconding the first recommendation, defended the regulations of the Council and spoke of the system of the Royal Colleges as bad in its immediate results and bad in its tendencies.

Sir HUGH BEEVOR expressed the opinion that an incentive to a boy to occupy his last school year with medical study would be a bad thing for education.

Sir PHILIP SMYLY said that this subject was first brought to the notice of the Council by the Irish College of Surgeons who complained that the period of professional study was being cut down from five to four years. The question here was a question of competition downwards. It was also a pecuniary question, because parents were anxious to know where they could get the cheapest education for their sons. Mr. Bryant had told them that they had required the preliminary subjects to be taken before the five years began and they had stopped it because the Royal Colleges found it would not pay.

Dr. PETTIGREW said he regretted exceedingly that the Royal Colleges had put themselves in this position, which he considered an entirely false one. The effect of the action of the Council had been to screw up the schools to give better education, and it would, in his opinion, be unfair to those schools if this Council recognised secondary education.

Sir CHRISTOPHER NIXON expressed his concurrence in the recommendation of the committee. The Royal Colleges maintained, he said, that the Council were alone an administrative body, that they had no constructive or legislative powers, and that they had no right to make rules or regulations or any form of requirement. In other words, they held that the Council had all along been acting upon a false assumption of authority. In such circumstances he saw nothing for it but to follow the recommendations of the committee and take the opinion of their legal advisers. As for the representatives of the two Colleges he did not think their action was perfectly consistent. While they denied the right of the Council to interfere in this matter they claimed for the Council the right to inspect, not only the final examinations of the Apothecaries' Hall of Dublin, but also the earlier examinations of that body.

Mr. BRYANT said he did not propose now to discuss the report of the committee. No doubt it was a most interesting document and drawn up with a view to support a certain resolution of the Council. He felt that the Council could not be in the right position to come to a proper decision on the matter until they had had an opportunity of studying the memorandum of the Royal Colleges. In this memorandum the case of the Royal Colleges was stated. He was sorry the document had not been printed as an appendix to the report. The committee were supplied with copies and more copies could easily have been furnished for the other members of the Council. In the peculiar circumstances of the situation he moved the adjournment of the debate until the November session.

Dr. MCVAIL objected to this. This question affected all the bodies throughout the country and adjournment only meant that the two Royal Colleges in England were to go on for another six months in the way they had been doing. If the Council were going to play with this question he saw no reason why the other bodies should not follow the example of the English Colleges.

Mr. BROWN thought the Council should have both sides clearly before them before they decided this important question.

Mr. HORSLEY said that adjournment of the debate would not impair the position which the Council almost unanimously took up last session.

Sir WILLIAM GAIRDNER said he had no objection to these preliminary subjects being taught in schools so long as there was no interference with the medical curriculum.

The motion for the adjournment of the debate was then put and agreed to.

Mr. BRYANT explained that he had got up several times during the debate to move the adjournment, but had not had an opportunity of speaking.

Mr. HORSLEY asked whether the Royal College of Physicians of London would furnish the Council with the opinion of their standing counsel.

Sir DYCE DUCKWORTH said he would consult the College upon that point. For himself he thought the memorandum gave all the information that was necessary.

The PRESIDENT said that if the Council would give him leave he would ask Mr. Muir Mackenzie to state his opinion on the whole question. He thought that it would be a good thing for Mr. Muir Mackenzie to see the legal opinion which had been given to the Royal Colleges and such of the other documents as might be necessary.

Dr. MCVAIL: Very good.

Dr. MACALISTER moved that the memorandum of the two Colleges be entered in the minutes as an appendix to the report of the Education Committee.

Mr. BRYANT said he had no objection to this being done.

The motion was agreed to by the Council.

On the suggestion of Dr. MACALISTER the third recommendation of the committee was agreed to. In this connexion Dr. MACALISTER gave the assurance that no disputed questions would be raised.

The University of Birmingham.

On the recommendation of the Education Committee the proposed Matriculation Examination of the University of Birmingham was added to the list of recognised Preliminary Examinations.

Medical Act for Jersey.

The Education Committee presented a report with comments on an Act passed this year by the states of Jersey dealing with the practice of medicine and surgery in that island. The President was requested to forward the comments to the Lord President of the Privy Council.

Restorations to the Dentists Register.

The Executive Committee reported that the prescribed conditions in each case having been duly fulfilled the names of the under-mentioned persons had been restored to the Dentists Register, from which they had been erased in conformity with the provisions of Section 12 of the Dentists Act:—Herbert George Blackmore, Hamersley Campbell, Victor Massey-Crosse, William James O'Hara, and William Henry Smith.

The Society of Apothecaries Title.

Mr. BRYANT presented a report from the special committee appointed to consider letters from Mr. James R. Upton, clerk to the Society of Apothecaries of London, on the subject of the use of the titles physician and surgeon. The committee reported that—

> They are not prepared to recommend that the funds of the General Council should be employed to guarantee, in conjunction with the Society of Apothecaries, the expenses of the plaintiff and defendant respectively in a test case to determine, by the Court of Appeal or the House of Lords, whether a Licentiate of the Society of Apothecaries is entitled to describe himself as physician or surgeon.

Seconded by Mr. HORSLEY, Mr. BRYANT moved that the report be received and entered on the minutes and that the recommendation contained in it be adopted.

Sir HUGH BEEVOR remarked that the Society of Apothecaries would have been pleased if this question could have been taken on the higher plane of the General Medical Council assisting in obtaining a decision, but in this instance they would be content to take their own course.

The motion was passed.

The Pharmacopœia.

The Council ordered strangers to withdraw so that they might receive *in camerâ* an opinion by the Council's legal adviser on the question of the copyright of the British Pharmacopœia.

Appointment of Solicitor.

The Council also sat *in camerâ* to receive a report from the Executive Committee in regard to the appointment of a standing solicitor to the Council in the room of Mr. F. W. Farrer, resigned. They appointed Mr. W. H. Winterbotham, official solicitor to the Supreme Court.

Acknowledgment of Mr. Farrer's Services.

On the motion of Sir DYCE DUCKWORTH, seconded by Mr. BRYANT, the following resolution was agreed to:—

The Council desires to record its warm appreciation of the services rendered to it for so many years by Mr. F. W. Farrer in his capacity as standing solicitor and to express its regret that the state of his health no longer permits him to assist the Council.

Appointment of Registrar.

Dr. MACALISTER, reminding the Council that under the Standing Order the appointment of general registrar was an annual one, moved the appointment of Mr. H. W. Allen till the closing day of the May session of 1901.

The motion was unanimously passed.

Appointment of Committees.

The Council's committees were re-arranged as follows:—

Executive Committee.—Sir Dyce Duckworth, Mr. Bryant, Dr. MacAlister, Dr. Glover, Dr. Heron Watson, Sir William Gairdner, Dr. Lombe Atthill, and Sir Philip Smyly, with Sir William Turner, the President of the Council, as an *ex-officio* member.

Penal Cases Committee.—Mr. Bryant, Mr. Tomes, Dr. Glover, Mr. Horsley, Dr. Heron Watson, Dr. Bruce, Sir C. Nixon, and Sir William Thomson.

Examination Committee.—Members nominated by the English Branch Council: Sir Dyce Duckworth, Mr. Bryant, and Mr. Teale; nominated by the Scottish Branch Council: Dr. Heron Watson, Dr. Pettigrew, and Dr. McVail; nominated by the Irish Branch Council: Sir Philip Smyly, Sir William Thomson, and Dr. Little.

Education Committee.—Members nominated by the English Branch Council: Dr. MacAlister, Dr. Glover, and Dr. Payne; nominated by the Scottish Branch Council: Sir John Batty Tuke, Sir William Gairdner, and Dr. Reid; nominated by the Irish Branch Council: Sir Christopher Nixon, Sir William Thomson, and Dr. Bennett.

Public Health Committee.—Members nominated by the English Branch Council: Mr. Power, Mr. Teale, and Dr. Pye-Smith; nominated by the Scottish Branch Council: Dr. Bruce, Dr. McVail, and Dr. Hector Cameron; nominated by the Irish Branch Council: Sir Philip Smyly, Dr. Bennett, and Mr. Tichborne.

Pharmacopœia Committee.—Dr. Leech, Sir Dyce Duckworth, Dr. Lombe Atthill, Dr. MacAlister, Sir John Batty Tuke, Mr. Tichborne, Dr. Payne, and Dr. McVail.

Dental Committee.—Sir William Turner, Sir Dyce Duckworth, Dr. Heron Watson, Mr. Tomes, and Sir Philip Smyly.

Dental Education and Examination Committee.—Mr. Bryant, Dr. Reid, Mr. Brown, Sir Philip Smyly, Dr. Hector Cameron, and Mr. Tomes.

Students Registration Committee.—Sir Dyce Duckworth, Dr. Cameron, Dr. MacAlister, Sir Batty Tuke, and Sir William Thomson.

Finance Committee.—Sir Dyce Duckworth, Mr. Bryant, Dr. Heron Watson, and Dr. Bennett.

Dr. Pye-Smith and Sir Hugh Beevor acted as scrutineers of the ballot taken in the case of the Executive and the Penal Cases Committees respectively.

The Finances of the Council.

Mr. BRYANT submitted the report of the Finance Committee on income and expenditure for the year 1899 and comparison with former years. This report was as follows:—

The Finance Committee report that the income of the General and Branch Councils for the year ending Dec. 31st, 1899, was £10,405 11*s.* 6*d.*, and the expenditure for the same period having been £10,677 10*s.* there is a deficit of £261 18*s.* 6*d.* This is due to the fact that for the first time the solicitor's account for law expenses has been included as a liability for the year in which it was incurred, and therefore two years' law expenses are included in one year, which will not occur again. Had it not been for this there would have been a surplus of £350 4*s.* From Table A it will be seen that the fees received by the Branch Councils show a considerable increase, for £449 17*s.* 6*d.* more was received from that source by England, £133 9*s.* 6*d.* more by Scotland, and £120 5*s.* more by Ireland, making a total increase of £703 12*s.* In 1897 there was a decrease from the previous year of £779 12*s.* 6*d.*, and in 1898 a decrease of £114 5*s.* The net proceeds of the sale of the Pharmacopœia for the year were £1365 10*s.* 1*d.*, but there will probably be found to be a very considerable drop in this item at the close of the current year.

The items of increased expenditure will be found on Table B, and amongst these may be specified the following:—

(*a*) An increase of £113 6*s.* 6*d.* for various committees' fees and expenses, chiefly caused by the fees, £94 10*s.*, paid to the experts who assisted the Education Committee. Omitting this item, which, however, will appear again this year, the increase would have been only £18*s.* 16*s.* 6*d.*

(*b*) An increase of £103 13*s.* 7*d.* in miscellaneous printing, which is more than balanced by the decrease in General Council and Executive Committee Printing.

(*c*) An increase of £752 16*s.* for law expenses, which is explained above. Had the liability for 1899 been, as usual, omitted, the increase would have been £140 13*s.* 6*d.*

(*d*) An increase of £43 10*s.* for interest on the mortgage, due to the amount spent on the recent alterations.

(*e*) An increase of £215 12*s.* 6*d.* for the sinking fund, an item which will occur for 49 more years.

On the other hand a decrease may be noted:—

(*a*) In the fees to Members of the Council and Executive Committee, amounting together to £698 7*s.*

(*b*) In the Pharmacopœia.

(*c*) In the printing of Registers, the great expense of setting up caused by the new contract being now met.

(*d*) In miscellaneous expenses, those for 1898 having included the circular as to the employment of unqualified assistants.

Table C shows that the average yearly expenditure of the General and Branch Councils for the past seven years has exceeded the average yearly income by £677 16*s.* 9*d.*

On June 8th, 1899, a resolution was passed by the General Council, on the recommendation of this committee, that money spent in the preparation of the British Pharmacopœia should not be charged as part of the expenditure of the year, but that a separate Pharmacopœia account should be kept. In order to show what would have been the effect of this resolution had it been in force during the past seven years a new Table D has been compiled, which shows that what may be called the normal expenditure of the Council has exceeded its income on an average by £912 13*s.* 6*d.* There seems no probability of the Council's income being largely increased in the near future, but this year the receipts from the Pharmacopœia will probably show a very considerable decrease; the money for the sinking fund, £215, which should come out of income, will have to be found, and if the recommendations of the Special Finance Committee be adopted the sum of £500 will have to be paid over to the Irish Branch Council; moreover, next year the election expenses, which in 1896 amounted to £488, will have to be met and in due course the inspection of examinations will re-commence, so that the Council ought seriously to consider whether it is not possible to reduce its expenditure to a very large extent. At present the Council is spending capital to the amount of over £600 a year.

In order to show how it is that of recent years the Council's expenditure has so largely exceeded its income a special Table E has been drawn out, from which may be seen the amount received for registration fees, which is the chief source of income, and the amounts paid for fees to members, printing, legal expenses, and interest on mortgage during the two septennial periods 1886–1892 and 1893–1899. It will be noticed that whereas the receipts are practically stationary the expenditure has largely increased, and this is due to the greater amount of work which now devolves upon the Council; its sessions are perforce longer, its committees are more numerous, and most of them have programmes and reports which all tend to increase the cost of printing, in addition to which there are the numerous reports on the inspection of the examinations of the Apothecaries' Hall of Dublin; the legal business is also greater and the premises have had to be enlarged to meet the increased demands for committee rooms.

The percentage rate has risen from 71·69 to 85·61.

Of the sum of £3000 authorised for the additions to the buildings, £2150 3*s.* 11*d.* was expended last year, since the close of which £779 18*s.* 11*d.* has been paid out, and there is still a balance of £49 due to the builders on the contract, which will make a total of £2979 2*s.* 10*d.*

A new Table J shows the total amount spent on the purchase of the freehold and on the alteration and furnishing of the premises of the Council up to March 31st, 1900. It may be pointed out that the interest on mortgage, £696 4*s.*, together with the sinking fund, £215 12*s.* 6*d.*, the total of the two being £911 16*s.* 6*d.*, are practically the rent which the Council pays for its premises, from which may be deducted £250, the rent received for No. 16, Hanover-square, making the net total £661 16*s.* 6*d.* In 49 years from now the Council will be living rent free.

With regard to the Pharmacopœia, 1898, a special Table H has been drawn up, showing the receipts and expenditure since it was taken in hand. The net profits to the end of 1899 amount to £924 13*s.* 6*d.*, and as in future the account is to be kept separate the committee suggest that as the Council has now reaped a substantial profit the proceeds shall no longer be treated as income, but placed to the credit of the Pharmacopœia account, in order, as far as possible, to avoid drawing on the funds of the Branch Councils when a new Pharmacopœia is in preparation.

Table G shows the assets of the three Branch Councils and the dental fund at the close of the last three years respectively, but owing to Consols being taken at the market value on Dec. 31st in each year it is very difficult to draw any conclusions as to increase or decrease and it might be well to follow the practice of many banks and in future value the stock at a fixed price, say £90, for the purpose of comparison.

Dental finance.—Table F shows that the receipts of the Dental Registration Fund for the year ending Dec. 31st, 1899, were £769 16*s.* 10*d.*, and the expenditure being £1101 10*s.* 7*d.* exceeds the income by £331 13*s.* 9*d.*, but in this account also the legal expenses for the two years are included and had it not been for this the excess of expenditure would have been £217 7*s.* 8*d.* The fund has latterly contributed more largely in paying its proportion to the fees paid to the General Council and this year the fees paid to the Dental Committee form a large item which is likely to be an annual one in future.

Mr. BRYANT moved that this report be received, entered on the minutes, and adopted.

Sir DYCE DUCKWORTH seconded the motion.

Mr. HORSLEY said that as the Council's resolution to grant £500 to the Irish Branch Council had been published in the minutes he begged to repeat to the Council what he had said in the committee—namely, that he entered his public protest against this expenditure. With regard to the report of the Finance Committee he did not propose any amendment, but it was scarcely possible to read a more awful report—a more terrifying report—because it showed that the Council's finances were in a hopeless state of confusion. At the present moment the Council did not know what their exact financial position was. That financial position

seemed to him to be without legal basis, for the Council were spending capital to the amount of over £600 a year. One of the tables accompanying the report showed that while the income in late years had remained stationary the expenditure had increased, the law expenditure as much as 108 per cent. during last year. With such expenditure before them how could this be called finance? He proposed to conclude by moving in accordance with a notice standing in his name on the paper.

The PRESIDENT pointed out that as the proposed motion was not in the nature of an amendment to the motion for the adoption of the report he thought the latter should be put to the Council before any new proposal was made.

The motion was then unanimously passed.

Mr. HORSLEY moved:—

That the whole question of the medical and dental funds of the General Medical Council and of the Branch Councils is again referred to the Finance Committee, together with the Trustees, whether members of the Council or not, and to report to the next session of the Council.

He said that the Council last session received alarming intelligence in regard to the finances and appointed a committee, such as he had mentioned in his motion, in order that the whole finance of the Council and Branches should be considered and a report given to the Council this session. He did not know why that committee had not carried out the instructions given to it, but had contented itself by granting £500 to the Irish Branch Council as a provisional measure. All he now asked was the re-appointment of the committee and that it should carry out its instructions. They could not discuss the matter unless they had a full detailed report from the committee and he hoped that would be forthcoming in November.

The PRESIDENT thought the Council should have a little more guidance. The motion was of the very widest kind. The whole medical and dental funds—their investments, capital, and income, and the various sources from which the income was derived—were brought within its scope, and he should like the treasurers to speak on the matter. If he had to carry out this proposal he should be slightly puzzled as to how to proceed.

Dr. BRUCE, who seconded the motion, said that the Council ought to know whether their financial position was improving or the opposite.

Mr. BRYANT, chairman of the Finance Committee, reminded the Council that their accounts were of necessity drawn up in a certain definite way because they were told by the Acts of Parliament how to divide their expenditure and show the different portions which were put out to the different Branches. Accordingly they had not a free hand. It was not a question of trouble at all, but he could not quite see how the Finance Committee could present more lucid statements than they did in present circumstances. However they might try to do better and make the accounts more clear, he was afraid that they should never succeed. They were certainly spending more than they received, but happily they had something to fall back upon, and the extra expenditure they had recently been incurring would, he thought, very shortly cease.

Dr. MACALISTER said that it was very difficult to know what particular questions had to be answered. He, also, should like a little more light thrown upon the meaning of the proposal and the matters that it was desired should be investigated. He thought that inquiry into the question what should be done with the Irish Branch Council was all that the committee had been asked to do. Whatever was wanted should be expressed.

Sir DYCE DUCKWORTH said it was quite clear that members of the Council did not study the tables of accounts. Some of the points which had been referred to in the discussion were set out on one of these tables, that giving a comparative statement of income and expenditure for the last three years. He thought it was forgotten that all the expenditure which had been incurred was expenditure which the Council had sanctioned. Of course, they had been spending a great deal more than in the former years when they sat in confined and insanitary premises. Then they were spending more on prosecutions, and legal expenses must and did mount up; but, after all, these sums of money represented very great activity, and if the Council were to do their duty their expenditure was hardly likely to decrease. No doubt that for fitting up the Council's extended premises would come to an end, and they were not likely to have any such outlay for a while again. The accounts of course were extremely complicated, but he did not see what was to be done under the terms of the motion. If specific questions were put the committee would do their best to make things plain to the intelligence of those who wished to be informed.

Mr. HORSLEY said that he could not conceal his astonishment at the speeches which he had just heard. There had been no attempt whatever on the part of the treasurers to dissipate the idea that the Council were in a financially unsound state. They could not dissipate that, for it came out in their own report. As to making the position better, there was no suggestion whatever, while there was not a particle of information afforded as to the exact position. What was wanted was a full statement of that position.

After some further discussion,

Dr. GLOVER hoped that the Financial Committee would accept the motion and accompany it with some suggestion for the adjustment of the income and expenditure. There was no harm in the motion, and if a suggestion was furnished by the committee it would form a basis for such a discussion as Mr. Horsley wanted. No member of the Finance Committee would argue that the present position was a satisfactory one, and therefore he supported the motion.

The PRESIDENT, while not objecting to the motion, remarked that he considered it was too general and he would like to have it so definite that the committee would know what they had to report upon. He was very anxious to arrive at something which they could unanimously agree upon.

With the approval of his seconder Mr. HORSLEY consented to his motion being unanimously passed in the following terms:—

That the special Finance Committee be requested to consider and report on (1) the financial position of the General Council and its branches as regards assets and liabilities; (2) the relation of the income and expenditure of the Council and its branches for the last ten years; and (3) the measures that appear to be desirable to place the finances on a satisfactory basis.

The session terminated with a vote of thanks to Sir William Turner, which was moved by Dr. GLOVER, seconded by Mr. BRYANT, and acknowledged.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations have been admitted Members of the College and have received their Diplomas:—

Rudolph George Abercrombie, Cambridge University and St. George's Hospital; Henry Cyril Adams, St. Bartholomew's Hospital; Bertram Cecil Robert Aldren, Edinburgh University; Thomas Shaw Arbuthnot, New York, Edinburgh, and St. Bartholomew's Hospital; William Arthur Bailey, University College and Royal Infirmary, Liverpool; Eric George Battiscombe, London Hospital; Charles Thomas Baxter, Middlesex Hospital; John Cunningham Bell, University College Hospital; Guy Black, St. Thomas's Hospital; Herbert Blackmore and Charles Henry Bradbury, Owens College and Royal Infirmary, Manchester; Arthur Hastings Bostock, St. Bartholomew's Hospital; John Bradford and Arthur Edmund Carver, Cambridge University and St. George's Hospital; Charles Henry Bullen, Mason University College and Queen's and General Hospitals, Birmingham; Hewlett Breton, John Beresford Christian, and Sidney d'Alton Corbett, St. George's Hospital; John Brocas Chambers Brockwell and Edward Cohen, Guy's Hospital; Thomas Burfield, Cambridge University and St. Thomas's Hospital; Edward Revely Clarke, Cambridge University and St. Mary's Hospital; Arthur Cubley, General Infirmary, Sheffield, and University College Hospital; David Leighton Davies and Charles Maxwell Ekins, University College Hospital; Henry Bertram Dismore and Charles Edwards, Guy's Hospital; Meredith Sedgwick Doubble and John Maltby Edwards, Charing-cross Hospital; William Claughton Douglass, St. Bartholomew's Hospital; John Scarborough Dudding and Samuel Jonathan David Esser, London Hospital; Harold St. Clair Elliott, Cambridge University and St. Bartholomew's Hospital; Charles Hy. Fennell, Oxford University and Charing-cross Hospital; Charles York Flewitt and Horace Wilberforce Freer, Mason College and Queen's and General Hospitals, Birmingham; Matthias Frederick Foulds, Owens College and Royal Infirmary, Manchester; Hugh Watson Fox and Edwin Wallace Goble, Guy's Hospital; Walter Burgess Fry, St. Thomas's Hospital; Shridhar Bheekaji Gadgil, Universities of Bombay and Calcutta and University College Hospital; Joseph Marcus Garman, London Hospital; Francisco José Gomez, King's College Hospital; William Ernest Gribbell, St. Mary's Hospitll; Leslie Haden Guest, Owens College and Royal Infirmary, Manchester, and London Hospital; Ernest Cutliffe Hadley, Mason University College and Queen's and General Hospitals, Birmingham; Donald George Hall, Cambridge and Edinburgh Universities; James Eder Harper, Durham, Birmingham, Guy's, London, and Westminster Hospitals; Sydney George Harrison, Charing-cross Hospital; Arthur Charles Haslam, St. Thomas's Hospital; Colin Sadler Hawes, Francis

Musgrave Howell, and Hy. Warwick Illius, St. Bartholomew's Hospital; Samuel Hey and William Morgan James, Cambridge University and St. Bartholomew's Hospital; Alfred Hewetson, St. Mary's Hospital; Thomas Higson and John Hoyle, Owens College and Royal Infirmary, Manchester; John Lupton Holt and Norman Alexander Aylmer Hughes, Yorkshire College and General Infirmary, Leeds; Archibald Douglas Jameson, St. Thomas's Hospital; Iain Mackinnon Jefferiss, King's College Hospital; Frederick Arthur Johns and Alfred Jones, London Hospital; George Joseph Alexis Leclezio, St. Bartholomew's Hospital; Frederick Samuel Leech, University College Hospital; John Lewis Lock, Cambridge University and St. Thomas's Hospital; Frederick William Longhurst, St. George's Hospital; John Augustus Noel Longley, Mason University College and Queen's and General Hospital, Birmingham; Charles John Nepean Longridge, Owens College and Royal Infirmary, Manchester, and St. George's Hospital; William James Lord, University College and Royal Infirmary, Bristol; William Henville Lowman, King's College Hospital; Frederick John McCann, Edinburgh University and King's College Hospital; Louis Charles Martin and Ernest Alfred Miller, Guy's Hospital; Charles Cecil Wildman Mayo, University College and General Infirmary, Sheffield; Richard Milnthorpe, Yorkshire College and General Infirmary, Leeds; Arthur Hy. McNeill Mitchell, St. Mary's Hospital; Adolph Andreas Christian Möllar, College of Medicine and Royal Infirmary, Newcastle-on-Tyne; Richard John Morris, Queen's College, Cork, and St. Barthelomew's Hospital; James Robert Morton, London Hospital; Reginald Cuthbert Mullins, Oxford University and Guy's Hospital; Sheffield Hy. Morier Neave, St. Bartholomew's Hospital; Cyril Alfred Rankin Nitch, St. Thomas's Hospital; Thomas Christian Orford, Owens College and Royal Infirmary, Manchester; Lionel Edward Orton, and Edward Albert Bodenham Poole, Mason University College and Queen's and General Hospitals, Birmingham; William Pancknidge Pancknidge, Middlesex Hospital; Edward Melville Bruce Payne, Charles Roberton Porter, and Michael Foster Reaney, London Hospital; Sydney John Peake, King's College, Hospital; Thomas Massey Pearce, St. Bartholomew's Hospital; [Harold Cooper Pretty and Arthur Izod Sheldon, University College Hospital; Frederick Schofield Rhodes, Owens College and Royal Infirmary, Manchester, and Middlesex Hospital; Charles Haldane Denny Robbs, St. Bartholomew's Hospital; Frederick James Faulkland Rooke and John Salmon Smith, Middlesex Hospital; Cuthbert Fennessy Selous, St. Thomas's Hospital; Hugh Frederick Sheldon, Owens College and Royal Infirmary, Manchester; George Herbert Simpson, St. Mungo's College, Glasgow, and University College Hospital; Stephen Francis Smith and Alfred Bertram Soltau, London Hospital; Hy. Edmund Symes-Thompson, Cambridge University and St. George's Hospital; Percy Tatchell and Albert John Walton Wells, St. Bartholomew's Hospital; William Irwin Taylor, Trinity University, Toronto; Basil Hubert Howard Tripp and Hardy Vesey Wells, St. Mary's Hospital; Harold Arthur Upward, Cambridge University and London Hospital; Francis Peter Vieyra, Madras University; Cyril Charles Coleby Kirke White, St. Bartholomew's Hospital; Edward White, University College and Royal Infirmary, Bristol; Thomas Wood, Cambridge University and Middlesex Hospital; and William John Young, University College and Royal Infirmary, Liverpool.

UNIVERSITY OF LONDON.—At the M.B. Examination held in May the following candidates were successful:—

First Division.—Herbert Cecil Barlow, Westminster Hospital; John Thomas Dunston, Guy's Hospital; Alfred Gordon Ede, and Arthur Tregelles Pridham, St. Bartholomew's Hospital.

Second Division.—Cornelia Bonté Sheldon Amos, London School of Medicine and Royal Free Hospital; Thomas Anstey-Chave, St. Bartholomew's Hospital; Alfred John Vernon Betts, Westminster Hospital; Isobel Sarah Bryson, Royal Free Hospital; Lewis Cook, Westminster Hospital; David Leighton Davies, University College; Alexander Fraser, Guy's Hospital; Cecil Scarlett Frost, St. Bartholomew's Hospital; George Robert Harcourt, St. Thomas's Hospital; Francis Joseph Hasslacher, King's College; Ernest William Holyoak and John William Hunt, St. Mary's Hospital; William Sam Inman, University College, Sheffield; David Thomas Cadvan Jones, University College; Charles Voughton Knight, St. Bartholomew's Hospital; Charles James Izzard Krumbholz, University College; William Henville Lowman, King's College; Maurice Taylor Male, University College; Ernest Alfred Miller, B.Sc., Guy's Hospital; Frank Mayo Morris, London Hospital; Richard Rothwell Mowll, King's College; Harold Rothery Nutt, St. Mary's Hospital; George Chetwode Owsley, Guy's Hospital; William Pancknidge Pancknidge, Middlesex Hospital; Thomas Perrin, St. Thomas's Hospital; George Edward James Antoine Robinson, University of Dublin and Royal College of Surgeons, Ireland; Henry Harold Scott, St. Thomas's Hospital; Nigel Frampton Stallart, University College; William Stuart Vernon Stock, University College, Bristol; Rhys Tudor Thomas, University College; Robert Lewis Thornley, St. Bartholomew's Hospital; Sydney Gordon Tippett, Westminster Hospital; Frank Douglas Turner, Guy's Hospital; and Lewis Augustus Walker, St. Bartholomew's Hospital.

N.B.—The foregoing list, published for the convenience of candidates, is provisional only, and is not final until the reports of the examiners shall have been confirmed by the Senate.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Fellows held on June 4th the following were elected for the ensuing year:—President: Mr. T. Myles. Vice-President: Mr. L. H. Ormsby. Honorary Secretary: Sir Charles Cameron, C.B. Council: Mr. A. H. Jacob, Sir Philip Smyly, Sir William Stokes, Mr. H. R. Swanzy, Mr. E. H. Bennett, Sir Charles Cameron, C.B., Dr. A. Meldon, D.L., Mr. C. B. Ball, Mr. R. L. Swan, Sir William Thomson, Mr. J. B. Story, Mr. J. Lentaigne, Mr. A. Chance, Mr. J. J. Cranny, Mr. R. D. Purefoy, Mr. H. G. Sherlock, Mr. R. B. McCausland, Mr. Graves Stoker, and Mr. F. Conway Dwyer.

UNIVERSITY COLLEGE, BRISTOL.—A laboratory has been established in connexion with the bacteriological department in which the examination of all kinds of morbid material is undertaken for medical men. Arrangements have also been made for medical men and others personally to undertake experiments in the laboratory.

DEATH FROM THE STING OF A BEE.—Mr. Greenaway, "bee expert" to the Monmouthshire County Council, and his niece were visiting the stock of bees belonging to a clergyman near Chepstow on May 21st, when the young lady was stung by a bee and she expired within half an hour afterwards. Medical evidence showed that death resulted from cardiac syncope produced by the sting, and at the inquest a verdict to that effect was returned.

PRESENTATION TO A MEDICAL MAN.—Mr. David Thomas, F.R.C.S. Eng., L.R.C.P. Lond., of Manly, Sydney, New South Wales, prior to his leaving in January last for some months on account of ill-health, was presented with a testimonial and a purse containing 195 sovereigns to be expended in London on the purchase of a suitable gift from the "people of Manly." He was also the recipient of a smoker's companion from his club patients.

THE CHARING-CROSS HOSPITAL EXHIBITS AT EARL'S COURT.—In connexion with the article on the Charing-cross Hospital Exhibits at Earl's Court which appeared in THE LANCET of June 2nd (p. 1607), we think it right to add a few words of acknowledgment of the valuable assistance rendered by Mr. Marcus E. Collins, architect, of 61, Old Broad-street, E.C., one of the vice-presidents of the hospital, who undertook the organisation and architectural arrangements of the exhibits.

A QUESTION OF VACCINATION.—At the Taunton police-court on May 26th a medical practitioner of the town was charged with having signed a certificate stating that a child was successfully vaccinated, such certificate being false. The board of guardians prosecuted and two of the district medical officers proved that the child was not successfully vaccinated. The defendant pleaded guilty and was fined £3 10*s*. He said that he had vaccinated the child but owing to illness could not see if the operation was successful and so he gave the certificate on the statement of the mother.

THE PROPOSED MEMORIAL TO THE LATE MR. G. J. SYMONS, F.R.S.—At the invitation of the president of the Royal Meteorological Society a meeting was held at the rooms of the society on Thursday afternoon, May 31st, to consider the question of a memorial of the late Mr. G. J. Symons, F.R.S., the distinguished meteorologist and founder of the British Rainfall Organisation. It was resolved unanimously that the memorial should take the form of a gold medal, to be awarded from time to time by the Council of the Royal Meteorological Society for distinguished work in connexion with meteorological science. The meeting appointed an executive committee representing many of the societies with which Mr. Symons was associated to take the necessary steps to raise a fund for that purpose. Contributions will be received by the assistant-secretary, Mr. W. Marriott, 70, Victoria-street, Westminster.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ADAMS, A. J. B., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

ASH, THOMAS LINNINGTON, L.R.C.P. Edin., M.R.C.S., L.S.A., J.P., has been appointed a Member of the Examining Staff of the St. John Ambulance Association.

ATKINS, SYDNEY ERNEST, L.R.C.S. Irel., L.S.A. Lond., has been appointed Medical Officer of Health and Public Vaccinator for the North Lew District by the Okehampton (Devon) Board of Guardians.

BEALE, H. R., L.R.C.P., M.R.C.S., has been appointed House Physician to St. Thomas's Hospital.

BENNETT, F. T., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Ham and Coombe Sanitary Districts of the Kingston Union.

BERRY, T. P., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Second Assistant Medical Officer of the St. Saviour's Infirmary, East Dulwich-grove, vice J. W. Pridmore, resigned.

BEVAN, A., L.R.C.P., M.R.C.S., has been appointed Senior Obstetric House Physician to St. Thomas's Hospital.

BLACK, G., L.R.C.P., M.R.C.S., has been appointed a Clinical Assistant in the Special Department for Diseases of the Skin at St. Thomas's Hospital.

BOURDAS, E. C., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

CAVENAGH-MAINWARING, W. R., M.B., Ch.B. Adel., has been appointed Honorary Assistant Surgeon, also Honorary Joint Pathologist, of the Adelaide Hospital, South Australia.

COSTELLO, M. J. B., M.B., B.Ch. Irel., has been appointed Medical Officer for the Workhouse and Dispensary District of Glenamaddy.

COURT, E. P., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Sanitary District of Hambledon, Droxford Union, vice J. W. Jeram, resigned.

CUNNINGHAM, J. F., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

DALLEY, W. C., M.R.C.S., has been re-appointed Medical Officer and Public Vaccinator for the Syston Sanitary District of the Barrow-upon-Soar Union.

DUDGEON, L. S., L.R.C.P., M.R.C.S., has been appointed House Physician to St. Thomas's Hospital.

EVE, F. C., B.A., M.B., B.C. Cantab., has been appointed House Physician to St. Thomas's Hospital.

GATES, E. A., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

GILES, W. A., M.B., Ch.M. Edin., has been appointed Honorary Surgeon of the Adelaide Hospital, South Australia.

GIMSON, K. C., M.B., B.C. Camb., has been appointed Medical Officer *pro tem.* by the Witham Urban District Council.

HABBIJUM, E. T., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Second Sanitary District of the Parish of St. George-in-the-East, London, vice E. M. Thuresson, resigned.

HARWOOD, H. M., M.A., M.B., B.C. Cantab., has been appointed Assistant House Physician to St. Thomas's Hospital.

HAMILTON, A. A., M.B., Ch.B. Dubl., has been appointed Honorary Assistant Physician of the Adelaide Hospital, South Australia.

HAMILTON, J. A. G., M.B. Dubl., L.R.C.S. Edin., has been appointed Honorary Assistant Gynæcologist, Adelaide Hospital, South Australia.

HAWKINS, C. L., M.A., M.B., B.C. Cantab., L.R.C.P. M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

HAY, T. W., M.B., C.M. Glasg., has been appointed Medical Officer for the No. 5 Sanitary District of the Newcastle Union, vice T. Scotland.

HAYWARD, W. F., L.K.Q.C.P. Irel., M.R.C.S., has been appointed Honorary Physician of the Adelaide Hospital, South Australia.

HEDLEY, E. W., M.A., M.B., B.C. Cantab., has been appointed House Physician to St. Thomas's Hospital.

HOWLETT, B. F., L.R.C.P., M.R.C.S., has been appointed Junior Obstetric House Physician to St. Thomas's Hospital.

JAY, M. R. H., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Assistant Surgeon of the Adelaide Hospital, South Australia.

JONES, A. WEBB, L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

KELSON, W. H., M.D., B.S. Lond., F.R.C.S., has been appointed Honorary Surgeon in Charge of the Throat, Nose, and Ear Department, City Dispensary, London.

KING, J., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer of Health by the Bude and Stratton Urban District Council.

KINLOCH, R. B., L.R.C.P., M.R.C.S., has been appointed Assistant House Physician to St. Thomas's Hospital.

KNOWLES, BEATRICE, M.B., B.S. Lond., has been appointed Second Assistant Medical Officer for the new Infirmary by the Bethnal Green Guardians.

MARTIN, A. E., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

NITCH, C. A. R., L.R.C.P., M.R.C.S., has been appointed a Clinical Assistant in the Special Department for Diseases of the Skin at St. Thomas's Hospital.

POMFRET, H. W., M.D. Vict., F.R.C.S. Eng., has been appointed Medical Officer for the Eighth Sanitary District of the Ashton-under-Lyne Union.

POULTON, B., M.D. Melb., M.R.C.S., has been appointed Honorary Surgeon of the Adelaide Hospital, South Australia.

PRIESTLEY, C. E., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Workhouse of the Thingoe Union, vice C. S. Kilner, resigned.

ROBERTS, J. LLOYD, M.D., B.S., B.A., B.Sc. Lond., F.R.C.S., has been appointed Honorary Physician to the Liverpool Stanley Hospital, vice R. J. Richardson.

SELOUS, C. F., L.R.C.P., M.R.C.S., has been appointed a Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

SMITH, ALFRED CHARLES FESTING, L.R.C.P. & S. Edin., L.F.P.S. Glasg., Civil Surgeon, has been appointed *pro tem.* to the Medical Charge of Troops at Bull Point, Plymouth.

STACK, M. T., M.B., C.M. Glasg., has been appointed Medical Officer for the Wavertree Sanitary District of the West Derby Union, vice R. Wearing, deceased.

STREET, A. F., M.D. Camb., M.R.C.S., D.P.H., has been appointed Medical Officer for the Children's Home at Westgate-on-Sea.

SWIFT, H., M.D. Cantab., M.R.C.S., has been appointed Honorary Assistant Physician of the Adelaide Hospital, South Australia.

SYMONS, M. J., M.D., Ch.M. Edin., has been appointed Honorary Ophthalmologist of the Adelaide Hospital, South Australia.

TAKAKI, Y., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

TOMLINSON, W. R., L.K.Q.C.P. Irel., L.R.C.S., has been re-appointed Medical Officer of the Moree Hospital, New South Wales.

UNSWORTH, N., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

VERCO, J. C., M.D. Lond., F.R.C.S. Eng., has been appointed Honorary Physician of the Adelaide Hospital, South Australia.

WAY, E. W., M.B. Edin., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Gynæcologist to the Adelaide Hospital, South Australia.

WYCHE, E. M., L.R.C.P. Lond., M.R.C.S., D.P.H., has been appointed Medical Officer for the Haddenham Sanitary District of the Ely Union, vice B. H. Andrew, resigned.

Vacancies.

For further Information regarding each vacancy reference should made to the advertisement (see Index).

BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL, Woodchurch-road, Birkenhead.—House Surgeon for twelve months. Salary £100 per annum, with board, residence, and laundry.

BIRMINGHAM CITY ASYLUM, Rubery-hill, Barnt-green, S.O., Worcestershire.—Senior Assistant Medical Officer.

BEDFORD COUNTY HOSPITAL.—Senior House Surgeon for one year. Salary £100, with apartments, board, and washing.

BOROUGH OF BOOTLE, HOSPITAL FOR INFECTIOUS DISEASES.—Resident Medical Superintendent, unmarried. Salary £120 per annum, with board, washing, and apartments in the hospital. Applications to be addressed to the Chairman of the Hospital Sub-committee, Town-hall, Bootle.

BOROUGH HOSPITAL, Birkenhead.—Resident Junior House Surgeon. Salary £75 a year, with certain fees usually obtained.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—House Surgeon. Salary £120 per annum, with rooms and attendance (not board).

CARLISLE DISPENSARY (not Provident).—Resident Surgeon, unmarried. Salary £150 per annum, with apartments (not board).

CARMARTHEN UNION.—Medical Officer and Public Vaccinator, to reside at Conwil, for the Conwil (a Welsh) District. Salary £60, with certain extra medical fees. Applications to the Clerk, 7, Hall-street, Carmarthen.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Pathologist. Tenable, subject to annual re-appointment, for not more than three years.

COUNTY ASYLUM, Whittingham, Lancashire.—Junior Assistant Medical Officer, unmarried. Salary commencing at £125 per annum, increasing conditionally to £250, with furnished apartments, board, attendance, and washing.

CORPORATION OF BIRMINGHAM—CITY HOSPITAL, Lodge-road.—Assistant Medical Officer. Salary £120 per annum, with board, residence, &c.

COTSWOLD SANATORIUM FOR THE OPEN-AIR TREATMENT OF TUBERCULOSIS.—Assistant Medical Officer. Salary to commence at £120 per annum and all found. Apply to Dr. S. T. Pruen, Sherborne Lodge, Cheltenham.

COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer, unmarried. Salary commences at £125 per annum, with prospect of increase to £250, with furnished apartments, board, attendance, and washing.

CRAIGLEITH POORHOUSE AND HOSPITAL, Edinburgh.—Medical Officer, resident. Salary £100 per annum, with board and apartments. Apply to the Clerk, Parish Council Chambers, Castle-terrace, Edinburgh.

DENBIGHSHIRE INFIRMARY, Denbigh.—House Surgeon for 12 months. Salary £80, with board, residence, and washing.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon. Salary £100 a year, with board, lodging, and washing.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £110 a year, with board, lodging, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

BURROWS.—On June 2nd, at The Haven, Harrow, the wife of Harold Burrows, M.B., of a son who only survived his birth a short time.

GREY.—On June 3rd, at Strathtay, Perthshire, N.B., the wife of Harry Grey, M.B., C.M., San Remo, Italy, of a son.

PURVIS.—On May 30th, at Montague-villas, Coleraine-road, Westcombe-park, the wife of Alfred Purvis, M.R.C.S., L.R.C.P., of a daughter.

SMITH.—On June 3rd, at Lynton House, Warrington, the wife of Reginald Smith, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGES.

BAKER—HANCE.—On May 25th, at Holy Trinity, Bath, Albert Baker M.D., to Caroline, youngest daughter of the late Henry Hance, of Old Brompton, London.

LIVESAY—LEYDE.—On June 1st, at St. Giles's Cathedral, Edinburgh, Arthur W. B. Livesay, Surgeon, Royal Navy, Chatham Dockyard, to Sharlie E. Leyde, daughter of the late Otto T. Leyde, R.S.A., St. Bernard's-crescent, Edinburgh.

LOGAN—CHAMBERLAIN.—On June 6th, at the parish church, Solihull, Warwickshire, Roderic Robert Walter Logan, M.R.C.S., of Ashby-de-la-Zouch, to Frances Ethel, youngest daughter of George K. Chamberlain, of Leamington House, Malvern Wells.

SESSIONS—COLLINSON.—On June 6th, at the Friends' Meeting House, Halifax, Frederick Leonard Sessions, M.R.C.S. Eng., L.R.C.P. Lond., of Evesham, Wors., to Ethel Mary, only daughter of Joseph Collinson, of Halifax, Yorks.

SWAYNE—LYON.—On June 2nd, at All Saints', Upper Norwood, Francis Griffiths Swayne, M.A., M.B., of Church-road, Upper Norwood, to Etta Ellen, widow of G. K. Lyon, H.M.I.C.S., and third daughter of Warren Hastings D'Oyly, of Southsea and London.

WADE—GREGORY.—On June 2nd, at St. John's Church, Upper St. Leonards-on-Sea, Charles H. Wade, M.A. Oxon, M.R.C.S., F.L.S., of Royal-terrace, Southend-on-Sea, to Eva, only surviving child of the late Rev. A. T. Gregory, formerly rector of Trusham.

DEATHS.

FITZ-PATRICK.—On May 31st, at Sussex-gardens, Hyde Park, Thomas Fitz-Patrick, M.D., M.R.C.P.

MOGER.—About May 30th, suddenly, Frederick Slade Moger, M.R.C.S., L.R.C.P., of Finchley, aged 63 years.

STAMPER.—On May 22nd, at Pembroke-street, Pembroke Dock, South Wales, James Fenton Stamper, M.D., J.P., aged 62 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

WHERE MEDICAL ETIQUETTE IS IGNORED.

THE Bridgend and Cowbridge Board of Guardians have evidently no great passion for medical etiquette. The union covers a large area with two distinct classes of population. On the eastern side is the agricultural section, whilst the other district is maintained chiefly by collieries. They have a number of medical officers at various places, each having a prescribed district. At Maesteg Dr. John Davies is the medical officer for the union and his district adjoins that of the Tondu and Aberkenfig, where Dr. Jones acts as the medical officer. Dr. Jones is also the "works doctor" for the neighbouring collieries under Messrs. North's Navigation Company and Dr. Davies until recently filled a similar position at Maesteg. Thus in these dual offices both medical gentlemen were on the best of terms and in constant communication with each other. Some time ago a man employed at North's Collieries, Tondu, was injured. He was attended upon by Dr. Jones as the works medical officer. He resided at the extreme end of Dr. Davies's parish district. A protracted illness necessitated the injured man applying for the pittance doled out by the administrators of relief. He had a daughter at home whom the guardians in their wisdom thought should be in service, and as the case, so far as the guardians were concerned, was in Dr. Davies's district they instructed him to inquire whether she was not fit to earn her own living. Dr. Davies, knowing that Dr. Jones was attending, sent the inquiry on to him and he replied that she was not fit for service. When this report was read out at the meeting of the guardians a few weeks ago Dr. Davies was asked to explain why he had not made his own report on the case and was also told that he must attend a meeting of the guardians. Dr. Davies gave his reason for not attending personally on the case to the effect that as Dr. Jones was then attending at the house such a visit was hardly necessary. It was explained by one of the guardians that there was an arrangement between the two medical officers. Dr. Davies was also unable to be present at the meeting. This, however, did not appease the more precise members of the guardians and by a resolution of the members Dr. Davies was informed that if he had no better explanation to give the matter would be reported to the Local Government Board, and the chairman added to this that Dr. Davies must attend the first possible meeting of the board. This interview took place recently and the medical officer explained that he could not examine the girl himself knowing she was under treatment by Dr. Jones. Such a course would be highly improper for any medical man to do. The chairman of the board (Archdeacon Edmondes), however, did not agree with this and pointed out that whenever an order was sent to an officer of the board they expected him to comply with that order and not take the version of another medical man. Dr. Davies pointed out the difficulty which would arise and the friction which must ensue by the board's medical officer attending a case which was under treatment by the works doctor and that it would be a grave breach of the etiquette of the profession. This, however, was not regarded in the same light by the board and although they accepted the medical officer's explanation in this case they gave him clearly to understand that the orders of the board were inexorable and they neither regarded the etiquette nor friction of the profession, but that their instructions must be rigidly observed.

"WORD BLINDNESS."

To the Editors of THE LANCET.

SIRS,—Could not raised type, or that used by the blind, be employed by sufferers from this deficiency? Might not experiments on these lines prove instructive? Possibly by these means the patients might be so much assisted as ultimately to learn to read in the ordinary way. For information as to whether this has ever been attempted I should be much obliged. I am, Sirs, yours faithfully,

Upper Bedford-place, W.C., June 2nd, 1900. C. G. S. MENTEATH.

THE CONCILIATION BOARD.

To the Editors of THE LANCET.

SIRS,—For the last few years letters have constantly appeared in the medical journals touching upon the question of club doctors and their pay. It is now, I believe, proposed that a conciliation board shall be constituted for the purpose of discussing the matter in conjunction with delegates from various friendly societies. What good will it do? Indeed, I would ask if there are not gentlemen upon the Council of the British Medical Association who themselves take club patients on the lowest possible terms of remuneration. If this be the case (and it certainly is so in one instance) how can one wonder that men who do not hold such an exalted (?) position in the medical world should do the same? No, Sirs, the remedy is with the club doctor himself. Let him refuse to accept club patients on the terms dictated by the clubs and things, I am inclined to think, would soon be altered, but so long as club doctors take office in clubs as treasurers, committeemen, &c., and attend their annual dinners and

make speeches in which they express their pleasure at being allowed to hold the position of surgeon and generally lead the club members to think what a blessing such a position is, so long will the clubs pay what they do and at the same time be under the impression that such a payment is adequate. Last Christmas, owing to the amount of work done in the previous year, and also owing to the fact that farmers and their sons were members, I resigned two clubs with the result that most of the members, if not all, are now my private patients, and I have received from them in cash this year more than I should have received for the whole year had I still continued to doctor for the two clubs.

I am, Sirs, yours faithfully,

May 29th, 1900. X. Y. Z.

"THE CASE OF THE LATE MR. ALFRED BOURNE."

To the Editors of THE LANCET.

SIRS,—I am requested to thank you for the insertion in THE LANCET of May 26th (p. 1566) of the list of subscriptions to the above fund. I enclose a second list, and we shall be very grateful if we may again trespass on your valuable space and kindness.

We are, Sirs, yours faithfully,

G. YEOMAN,

pp. J. A. Hutchinson, M.D. Durh., and others.

INTOLERANCE.

To the Editors of THE LANCET.

SIRS,—I shall be glad if you will give me your opinion and advice on the following case and if you will kindly insert my letter in your correspondence columns. A is the only qualified man residing in a certain village where there are a number of works, collieries, &c. He is in attendance for a considerable time on all of the employés. A section of the population belongs to a certain religious denomination of which A is not a member. They determine to have a man of their own creed and with this object introduce a qualified man B. Some of the leading officials are co-religionists of B's and they use all their influence to substitute B in place of A as medical attendant to the men employed in the collieries, &c., to which they (the officials) belong. Many of the men object to employ the newcomer as they have every confidence in A, and, also, they naturally argue that every man should be at liberty to employ the professional services of whomsoever he chooses. The adherents of A hold several meetings and requests are forwarded to the different works that A shall continue to receive the money periodically paid in for medical attendance on the men. The officials, friends of B, offer the men an ultimatum—that they shall transfer their subscriptions to B or else take a month's notice to leave their employment. Most of the men submit to the wishes of the officials, but many privately engage the services of A, refusing to be attended by B, to whom, nevertheless, they are still compelled to pay their subscriptions. Those who refuse to pay him are discharged from their employment. Having placed all the circumstances of the case before you I will now ask you, Sirs, firstly, is not such coercive action on the officials' part contrary to English law; is it not, in fact, a violation of the terms of the Truck Act? and, secondly, if such conduct is illegal to whom should complaint be made—the Board of Trade or the General Medical Council?

I am, Sirs, yours faithfully,

June 5th, 1900. VIGILANS.

* * The Truck Act prevents the practice of paying the wages of workmen in goods instead of money. We doubt if the action of the official is a violation of this Act, but only a lawyer can express an opinion. If legal confirmation of the view that the Truck Act has been violated is forthcoming the plaintiffs would have to be the workmen.—ED. L.

"DRUG HABITS."

To the Editors of THE LANCET.

SIRS,—A correspondent in THE LANCET of June 2nd, p. 1634, writes on the above subject: "Now the proper and humane treatment is to give the drug in gradually diminishing doses and not to totally withdraw it"; and, again, "The medical man should think of the suffering and perhaps death that may follow its sudden withdrawal." This teaching seems to be a continuation of the old teaching of the late Dr. Watson who, writing of alcohol, says: "Give him a hair of the dog that bit him." The late Sir Andrew Clark used to teach that "alcohol and all drugs when they were taken in excess were all alike—poisons," and that they should be entirely and immediately withdrawn. I have acted on this advice for over 20 years and have never yet had reason to regret my action. Still, the sad fact remains that many still follow the old routine and, what is more, they believe in it, and certainly in alcoholic cases frequently take away the only chance of curing their patients. The view of your experienced readers would be very interesting.

I am, Sirs, yours faithfully,

Putney, S.W., June 5th, 1900. A. S. MORTON, M.D. Durh.

WE have a paper marked for insertion detailing a fatality to a woman in a laundry. Will the author kindly send his name and address, which have not been affixed to his manuscript?

Reformer.—The person is not a medical man, but in the present state of the Medical Acts no penalty attaches to his giving medical aid unless he pretends to be a medical man, and even then a prosecution might not result in a conviction. As he is not a member of the medical profession he of course cannot be prevented by the General Medical Council from advertising.

W. M.—The assistant should clearly not make such statements.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Anthropological Institute of Great Britain and Ireland; Mr. W. Armstrong Buxton; Messrs. Allen and Hanburys, Lond.; Messrs. Armour and Co., Lond.

An Address

ON

THE VALUE OF TUBERCULIN IN DIAGNOSIS AND TREATMENT.

Delivered at the Medical Graduates' College and Polyclinic on Feb. 9th, 1900,

BY T. McCALL ANDERSON, M.D. GLASG,
PROFESSOR OF CLINICAL MEDICINE AND DEAN OF THE MEDICAL FACULTY IN THE UNIVERSITY OF GLASGOW.

GENTLEMEN,—When the council of this institution did me the honour of inviting me to give a clinical lecture I had some difficulty in complying with their request because the clinical material at my disposal in Glasgow was not available and I had neither time nor opportunity in the midst of my work as examiner for the Army Medical Service to select on the spot cases suitable for my purpose. But it occurred to me that, instead of complying with the letter of their request, I might deal with some subject of practical interest, and with their consent I now propose to refer shortly to the value of tuberculin in diagnosis and treatment—a therapeutic measure in which from the first I have taken a deep interest and of which I have had considerable experience.

Most of us remember the intense enthusiasm with which Koch's great discovery was greeted and it was then the confident expectation of the public—if not of the profession—that the days of tuberculous disease were numbered. The consequence of such anticipations, as might have been expected, was that this powerful agent was too often employed in a reckless and indiscriminate manner. Patients were dosed with it on wholesale principles, often without due reference to the suitability of their cases, and the amount administered was generally unduly high, or too frequently repeated, thus leading to inevitable disaster. It is not surprising, therefore, that the extravagant laudation with which the discovery of Koch was hailed soon gave place to an equally absurd depreciation of its merits. Indeed, I am probably within the mark when I say that there are very few medical men in this country at the present time who are in the habit of using tuberculin. At all events, I can say that amongst the 40 medical officers attached to my own hospital it is not used by any of them. After a pretty wide experience I see no reason to resile from the opinion which I ventured to express in 1890—that the discovery of tuberculin "marked the commencement of a new era both in diagnosis and therapeutics."

In the recent discussions which have taken place throughout this country on the means to be adopted for the prevention of tuberculosis, one of the points most insisted on was the necessity of preventing the sale of tuberculous meat, and, above all, of the milk of tuberculous cows, and with practical unanimity it was conceded that the injection of tuberculin was a very certain test of the presence or absence of tuberculous disease in animals. How is it, then, that the tuberculin test is confidently relied upon by veterinary surgeons for the diagnosis of tuberculosis in animals, while medical men who applaud the use of it in animals with rare exceptions fail to take advantage of it in human beings when a doubt exists as to the diagnosis? Possibly it may be owing to the belief that though useful in the case of animals it is not to be relied on in the case of man, or that it would be an unsafe procedure in the latter. But I can say that if used with reasonable care it is both efficient and safe in the human subject. I could give many illustrations of its value in diagnosis but two will suffice, the first of which at the same time illustrates its curative power, though not quoted for that purpose.

CASE 1. *Tuberculin as a diagnostic test.*—A servant girl, aged 19 years, was admitted into the Western Infirmary of Glasgow on Jan. 15th, 1898. Her family history was excellent except that one brother, aged four years, was said to have died from tuberculous peritonitis. With regard to the patient's history, two years before admission a small, dark red, almost livid spot appeared on the outside of the left thigh which gradually healed in the centre and spread at the edges; the surface was dry and scaly and there was neither pain nor itching. Shortly afterwards a similar patch appeared below the knee which ran a like course, but it had healed up before admission, a cicatrix, which was brown at the edges, being left. Nine months before I saw her pustules formed in the centre and at the upper part of the first patch, which ended in ulceration. The ulcerated surface continued to discharge a thick yellow pus and undermined the skin, which had a livid tint. The diagnosis lay between hereditary syphilis and tuberculous disease. As I was inclined to think that it was probably tuberculous I determined to test the point with tuberculin. The first injection of the old tuberculin was given on Jan. 15th, but there was no decided reaction till the third dose of three cubic centimetres of a strength of 1 in 1000 was given on the 20th, which sent up the temperature to 100·4°F., while the fourth (same dose) on the 23rd sent it up nearly to 103°, thus leaving no doubt of the tuberculous character of the ulceration. This treatment was therefore continued till the end of February, there having been 21 injections in all (the initial injection being 0·001 cubic centimetre and the largest 0·175 cubic centimetre), the total quantity used being nearly one cubic centimetre of the undiluted tuberculin. The only other treatment was three ounces of cod-liver oil daily and she was dismissed quite well on March 24th, the whole duration of the treatment being about two months (chart shown).

CASE 2.—On June 2nd, 1899, a lad, aged 11 years, came under my care in the Western Infirmary of Glasgow complaining of weakness and of a swelling of two months' duration on the left side of the neck. His father and mother and nine of a family of 14 were alive, but one of these was suffering from "consumption of the bowels" and one from "decline." The five who died succumbed to chest complications in connexion with whooping-cough. Two months before admission the patient, who had always been pale and delicate, fell off a wall, and immediately thereafter began to complain of pain in the left side of the neck where a distinct swelling made its appearance. He was sick for a time after the fall, but in a few days the pain in the neck disappeared; the swelling, however, remained, although, according to the mother, it varied in size from day to day, and a week before he came to me it rapidly increased in size. The patient, on admission, was emaciated, pale, and anæmic, the hæmoglobin was 45 per cent., and the corpuscles numbered 4,000,000, there being no excess of white corpuscles. There was no fever, no œdema, and the urine was normal, but he complained of shortness of breath, palpitation, and pain across the abdomen on exertion, with occasional vertigo. The spleen was slightly enlarged, though its lower edge could not be felt, and the liver extended for an inch below the costal margin in the nipple line. There was slight enlargement of the inguinal, axillary, and submaxillary glands. The left submaxillary glands were greatly enlarged, forming a prominent mass in the left side of the neck, but the individual glands could not be distinguished. This mass was painful, freely moveable, and firm. He was sent to me as a case of lymphadenoma, but I suspected that the disease might be tuberculous and therefore tried tuberculin. The first four injections of ½ cubic centimetre, 1 in 1000, old tuberculin sent the temperature up to 102·2°F., 102·8°, 102·6°, and 102·4°, while a subsequent injection of one cubic centimetre, 1 in 1000, produced a temperature of 104·8°. There being, therefore, no doubt as to the nature of the case he was transferred to the wards of one of my surgical colleagues. (Chart shown).

It is a well-known fact that while physical signs often indicate with precision the seat of disease there is frequently tuberculous deposit elsewhere unaccompanied by symptoms of any kind and therefore overlooked. But here, again, with the aid of tuberculin we are able to ferret out and to localise unsuspected foci of disease, as in the following case.

CASE 3.—A man, aged 28 years, was admitted in the second week of January, 1891. He had had five attacks of hæmoptysis within 13 months, occurring at intervals of two or three months, and he had two anal fistulæ of nine months' duration. An examination of the chest showed entire absence of physical signs with the exception of *weakened respiratory murmur at the right base.* He was treated with the old tuberculin; 13 injections were given in all, the first of 2 cubic centimetres of 1 in 1000 on Jan. 16th and the last, 50 times stronger, on Feb. 17th. Before dismissal on March 13th the following report was made: "He

has had no hæmoptysis for six months and *râles which appeared along with much pain at the right base* after second injection gradually disappeared within a fortnight and there are now no physical signs. Both fistulæ have completely healed. There has been great improvement in the general health with an increase in weight of nine and a quarter pounds."

Many other cases of a similar nature might be mentioned. For example, in a case of lupus of the face the injection of tuberculin not only inflamed the face but also lighted up pain, tenderness, and swelling of the right elbow-joint, which, however, disappeared after a few injections, and in a case of phthisis, soon to be referred to, there were no evidences of disease in the right lung, and yet when the treatment was commenced moist râles appeared over an area of the size of a crown-piece near the right nipple, which, however, disappeared when the injections were given a few times. The curative power of tuberculin is well illustrated by the two cases already mentioned, but further proof of its beneficial influence is afforded by the cases which follow, the first two being cases of phthisis which benefited greatly from the treatment.

CASE 4.—A man, aged 34 years, was admitted into the Western Infirmary of Glasgow on Dec. 1st, 1897, on the recommendation of Dr. Service of Mossend. The only flaw in the family history was that one brother died from hæmoptysis at the age of 30 years. He had never been well since an attack of influenza three years before, and two years ago a short hacking cough set in, accompanied by a muco-purulent expectoration, in which he sometimes noticed blood. About this time also he began to lose flesh and during the last two years had lost two stones. For 18 months he had suffered from night sweats and during the last six had two attacks of hæmoptysis. For a few months, too, his strength had failed very much, and lately he had been almost unfit for work. Shortly before admission he was seen after a long interval by Dr. Service who wrote: "When I saw him I was greatly shocked at his appearance; he had the appearance of a dying man and came, as he said, that I might tell him the worst and how long he had to live." On admission he was found to be pale and emaciated, with no appetite, troubled with night-sweats and with much expectoration, in which tubercle bacilli were found in great abundance by Dr. A. R. Ferguson, but there was no fever. There were no physical signs in the right lung. Over the upper lobe of the left lung in front there were moderate flattening and defective movement, decided dulness, marked increase of vocal fremitus, and slighter of vocal resonance, whilst moist râles with tubular breathing were heard on deep inspiration. Tubular breathing was also detected in the supra-spinous region and moist râles between the scapula and the spine. At the base there were slight dulness and feeble breathing; indeed, there was no part of the lung which was altogether free from signs of disease. Dr. Service sent the patient to me with the view of having a course of tuberculin treatment, and although I did not consider the case a very hopeful one I decided to give him a chance with the new tuberculin, the only other treatment being cod-liver oil, up to three ounces per day. The first injection of $\frac{1}{10\,000}$th milligramme was given on Dec. 12th, 1897; the largest, two and a half milligrammes, on Feb. 26th, 1898; and the last of one milligramme on April 14th, the total amount used being about 31 milligrammes in 47 injections. From the time the treatment was commenced he improved steadily, more particularly as regards his general condition, and was dismissed at his own request on April 28th when the following report was taken; "The patient feels in good health; he can now read with comfort for hours whereas formerly his eyes soon got tired with reading; his appetite is completely restored; the night sweats have long disappeared; his cough and expectoration are almost gone; and he has gained about 1 st. 6 lb. in weight."

The after-history of the case is as follows. The last time I saw him was on July 14th when he visited me at my request. I found that he had not fallen off in any respect and that he had gained 7 lb. since dismissal, making a total gain of 2 st., his weight now being 12 st. 3 lb., which was his normal weight. He also stated that he could now do an ordinary day's work without fatigue. The improvement in the general was more marked than in the local condition. The expectoration showed that bacilli were still present, but in small numbers, and mostly found lying separately. The right lung remained healthy, while the condition of the left was as follows. The flattening, defective movement and dulness in front were not nearly so pronounced and the râles, though still present, were scanty; while between the scapula and spine they had entirely disappeared, only puerile breathing being heard. The dulness and feeble breathing at the base were hardly perceptible. In a letter which I received lately from Dr. Service he said: "When I saw him last at the beginning of this week he looked better than I have ever known him; he eats and sleeps well and has hardly any cough. I feel satisfied that, whatever his ultimate fate, he would now have been in his grave had it not been for the treatment which was followed. On my advice he is looking out for a situation abroad."

It will be observed that the tuberculin treatment was not steadily increased, owing partly to a change of assistant during its course and partly to the stock of tuberculin having temporarily run out. The full dose, too, was not reached, two and a half milligrammes being the largest injection instead of the maximum of 20 milligrammes, because the patient felt so well as to desire to return home. The improvement, however, was so marked as to show undoubtedly the beneficial effect of the new tuberculin treatment even in pretty advanced cases. (Chart shown.)

The following case may also be referred to, although it is still under observation.

CASE 5.—A young man, aged 17 years, was admitted on August 5th, 1899. The family history was satisfactory, although a maternal aunt died from consumption. He was never very robust, but enjoyed fair health until 14 months before I saw him, when he caught cold, and he has had a cough at intervals ever since. In the spring of last year his cough became aggravated, and was accompanied for the first time by expectoration, which was "tough and yellow," and on one occasion blood-stained; and about two months before admission he suffered for a few days from a stabbing pain over the left breast, aggravated on coughing or taking a deep breath. He had lost flesh and strength and colour, was easily tired, and had complained occasionally of night sweats and of palpitation and breathlessness on exertion. In the right infra-clavicular region there was some flattening, defective movement, dulness and crackling râles, which were also present over the upper two-thirds of the back. The expectoration was abundant, muco-purulent, and contained tubercle bacilli in great abundance. There was no fever. He was put upon generous diet with three pints of milk and three ounces of cod-liver oil per day. He also had a subcutaneous injection of 10 minims of a saturated solution of picrotoxin at bedtime and was kept as much as possible in the open air. The night sweats soon disappeared, he felt stronger, and increased in weight, and by Nov. 11th all trace of râles had disappeared in front, but they were still very decided behind. On Nov. 12th, therefore, a course of the old tuberculin was commenced and is being still continued. The last report was taken on Jan. 12th and is as follows: "There is still slight mucous expectoration, about one-eighth of what he had at first, containing tubercle bacilli, though in decreased numbers, but all trace of râles has disappeared and the physical examination of the chest reveals no definite physical signs. Since admission he has gained 1 st. 4½ lb., weighing 8 st. 12½ lb., being 9½ lb. above his normal weight before the commencement of his illness."

But the best class of cases for studying the effects of the tuberculin treatment is that of external tuberculosis, because we can see the results which ensue. One of my resident medical officers (Dr. John Aitken) has kindly at my request tabulated the particulars of 45 consecutive cases admitted into the Western Infirmary of Glasgow from April, 1889, to April, 1899, and without any preconceived opinions. The following is a summary of the results. Of these, 35 were illustrations of lupus vulgaris, seven of scrofuloderma, and three of lupus erythematodes. All were treated with the old tuberculin with the exception of one in which the new (T.R.) tuberculin was used, and the only other treatment consisted of generous diet and from two to three ounces of cod-liver oil daily.

Of the 35 cases of lupus vulgaris 23 were females and 12 were males. The oldest patient on admission was 59 years of age and the youngest 10 years, the average being 23 years. The age of the youngest patient when the disease commenced was seven years and that of the oldest 28 years, the average age at commencement being 13 years. The duration of the disease when the patient was admitted was in one case as low as five months, while in another it had been present for no less than 46 years, the

average duration being seven and a half years. In 32 of the 35 cases the face was involved, generally the nose prominently or exclusively, and, in several, other parts of the body or limbs were involved as well. In one case the right arm and neck were attacked alone, in one the left thigh and neck only, and in one the left leg was the part implicated. The duration of the tuberculin treatment varied from seven weeks to six months, but one patient, who was much improved when she left the hospital, could only be induced to remain for four weeks. The average duration of the treatment was four months. In 33 of the 35 cases the result is thus tabulated by Dr. Aitken: Improved, two; much improved, eight; very much improved, seven; almost well, four; well, 12; total, 33. It will thus be observed that improvement was invariable, and the number of cases dismissed well would have been much greater had we been able to induce some of the patients to remain longer under treatment.

Of the seven cases of scrofuloderma—five being males and two females—the oldest patient on admission was 60 years of age, the youngest 9 years, the average age being nearly 22 years, or omitting the one aged 60 years, fully 12 years. The age at which the disease commenced varied from one to 49 years, the average age being fully 12 years. Its duration on admission varied from four to 13 years, the average being nearly nine years. The parts affected were: (1) the right leg and thigh, (2) the thigh and buttocks, (3) the right thigh, (4) the left thigh and scrotum, (5) the right ankle, (6) the cheeks and right arm, and (7) the left side of the face and neck. It will thus be observed that while in lupus the face is almost always involved, in scrofuloderma it generally escapes, the lower segment of the body being predominantly implicated. The duration of the tuberculin treatment in the latter varied from three to five and a half months, the average being nearly four months. The results are thus tabulated by Dr. Aitken—improved, one; almost well, one; and well, five.

The three cases of lupus erythematodes all occurred in females. The first of those patients was 31 years of age on admission, the nose and left cheek being involved for a period of 14 years; the second was 18 years old, and the disease had implicated the face, ears, hands, and arms for two years; while the third, aged 23 years, had suffered from it for three years, the cheeks, head, and knuckles being implicated. The duration of the tuberculin treatment was two and three-quarter months, two and a half months, and one and three-quarter months, and they were all dismissed well. In all of them the local and constitutional reactions were well marked. (Temperature charts handed round.) These results will be a surprise to many, and are even to myself, because I have not been equally fortunate in all the other cases of the same disease, but one positive outweighs many negative results.

From an early period of my professional life I have always taught that lupus vulgaris and lupus erythematodes were manifestations of the strumous diathesis, a view which was long opposed by the majority of experts. At the present time, however, the tuberculous nature of lupus vulgaris is generally conceded, while lupus erythematodes is almost universally considered to be independent of the strumous diathesis. The main grounds for this opinion are that the tubercle bacillus has not been found in the latter affection and that tuberculin injections yield no reaction and do no good. The cases, therefore, which I have just referred to are of special interest as supporting my view that lupus erythematodes is a member of the tuberculous family.

Now whether is tuberculin—as far as its therapeutical effect is concerned—to be regarded in the light of a constitutional or a local medication? That it produces constitutional symptoms we know, as witness the fever, the headache, and the sickness which so often follow its administration; but these are injurious rather than otherwise and the less we have of them the better. That it produces marked local symptoms we see in cases of external tuberculosis, for we observe after each injection redness, swelling, serous exudation, and crustation, accompanied by elevation of temperature at the part, and I think it cannot be doubted that it is this inflammatory action which puts the enemy to rout just as an attack of erysipelas of the face often improves, if it does not remove, a tuberculous affection of that part. If this be true then it follows that we must regard tuberculin treatment in the light of a local remedy, but one which does not rectify, but rather intensifies, the constitutional vulnerability. From this it is obvious that, as we aim at permanent results, we must not rest content with injecting tuberculin only but must combine it with general treatment.

Some of my professional brethren who have carried out the tuberculin treatment on a considerable scale—especially in the case of external tuberculosis—agree with me as to the immediately beneficial results of such a course of treatment, but state that after the course is completed there is generally a recrudescence of the malady. Now I freely admit that if patients are treated by means of tuberculin injections alone and then dismissed from hospital to miserable homes, where they are deprived of light, pure air, abundant food, and tonic treatment generally, a recrudescence of the disease is all but certain. For we must never forget that two factors have to be taken into account in dealing with tuberculous disease: (1) the tubercle bacillus; and (2) the soil favourable to its life and development. So that, in order to obtain permanent results, it is obvious that, in addition to the use of tuberculin, means must be taken simultaneously to change the soil upon which the micro-organism flourishes, such as good and abundant nourishment, living as much as possible in the open air, and the use of tonics, cod-liver oil, and other anti-strumous remedies. This combined treatment, if judiciously carried out, has, in my experience, yielded excellent results and I commend it to you with confidence.

In view of economy of material, especially in reference to the more expensive T.R. tuberculin, the process of diluting the remedy so as to meet the requirements of varying doses is somewhat troublesome. The following is the scheme which has been adopted in connexion with my department in the Western Infirmary of Glasgow and which perhaps may prove useful to others.

METHOD OF DILUTING TUBERCULIN ADOPTED IN PROFESSOR McCALL ANDERSON'S WARDS IN THE WESTERN INFIRMARY OF GLASGOW.

(Drawn up by Dr. John Macewen, Resident Medical Officer.)

Doses of Old Tuberculin.

Make up with ½ per cent. carbolic.

(*a*) Make up 5 cm. to 5 c.c = 1·1000

Doses ½ c.c. = $\frac{1}{2000}$ c.c. = $\frac{1}{200}$ c.c.
1 c.c. = $\frac{1}{1000}$ c.c. = $\frac{1}{100}$ c.c.
1½ c.c. = $\frac{3}{2000}$ c.c. = $\frac{3}{200}$ c.c.

(*b*) Make up 10 cm. to 5 c.c. = 1·500

Doses 1 c.c. = $\frac{2}{1000}$ c.c. = $\frac{1}{50}$ c.c.
1½ c.c. = $\frac{3}{1000}$ c.c. = $\frac{3}{100}$ c.c.

(*c*) Make up 20 cm. to 5 c.c = 1·250

Doses 1 c.c. = $\frac{1}{500}$ c.c. = $\frac{1}{125}$ c.c.
1½ c.c. = $\frac{3}{500}$ c.c. = $\frac{3}{250}$ c.c.
2 c.c. = $\frac{4}{500}$ c.c. = $\frac{2}{250}$ c.c.

(*d*) Make up 50 cm. to 5 c.c. = 1·100

Doses 1 c.c. = $\frac{2}{500}$ c.c. = $\frac{1}{100}$ c.c.
1½ c.c. = $\frac{3}{500}$ c.c. = $\frac{3}{200}$ c.c.

(*e*) Make up 100 cm. to 5 c.c. = 1·50
($\frac{1}{10}$ c.c.)

Doses 1 c.c. = $\frac{1}{100}$ c.c. = $\frac{1}{10}$ c.c.
1½ c.c. = $\frac{3}{100}$ c.c. = $\frac{3}{20}$ c.c.

(*f*) Make up 200 cm. to 5 c.c. = 1·25

Doses 1 c.c. = $\frac{2}{500}$ c.c. = $\frac{1}{25}$ c.c.
1½ c.c. = $\frac{3}{500}$ c.c. = $\frac{3}{50}$ c.c.
2 c.c. = $\frac{4}{500}$ c.c. = $\frac{2}{25}$ c.c.

(*g*) Make up ½ c.c. to 5 c.c. = 1·10

Dose 1 c.c. = $\frac{2}{500}$ c.c. = $\frac{1}{10}$ c.c. = maximum.

Doses of New Tuberculin.

Make up with 20 per cent. glycerine solution.

(*a*) Make up 1 cm. to 5 c.c. = 1·5000

Doses 1 c.c. = $\frac{1}{1000}$ c.c. = $\frac{1}{100}$ mg. = $\frac{1}{1000}$ mg. = $\frac{1}{250}$ mg.
1½ c.c. = $\frac{3}{1000}$ c.c. = $\frac{3}{200}$ mg. = $\frac{3}{1000}$ mg. = $\frac{3}{500}$ mg.

(*b*) Make up 2 cm. to 5 c.c. = 1·2500

Doses 1 c.c. = $\frac{2}{1000}$ c.c. = $\frac{1}{250}$ mg. = $\frac{1}{1000}$ mg. = $\frac{1}{250}$ mg.
1½ c.c. = $\frac{3}{1000}$ c.c. = $\frac{3}{250}$ mg. = $\frac{3}{1000}$ mg. = $\frac{3}{250}$ mg.
2 c.c. = $\frac{4}{1000}$ c.c. = $\frac{1}{250}$ mg. = $\frac{1}{1000}$ mg. = $\frac{1}{125}$ mg.

(*c*) Make up 5 cm. to 5 c.c. = 1·1000

Doses 1 c.c. = $\frac{2}{1000}$ c.c. = $\frac{1}{250}$ mg. = $\frac{1}{1000}$ mg. = $\frac{1}{100}$ mg.
1½ c.c. = $\frac{3}{1000}$ c.c. = $\frac{3}{250}$ mg. = $\frac{3}{1000}$ mg. = $\frac{3}{250}$ mg.

(*d*) **Make up 10 cm. to 5 c.c. = 1·500**

Doses 1 c.c. = $\frac{5}{100}$ c.c. = $\frac{5}{10}$ mg. = $\frac{500}{1000}$ mg. = $\frac{1}{2}$ mg.
1½ c.c. = $\frac{7.5}{100}$ c.c. = $\frac{7.5}{10}$ mg. = $\frac{750}{1000}$ mg. = $\frac{3}{4}$ mg.

(*e*) **Make up 20 cm. to 5 c.c. = 1·250**

Doses 1 c.c. = $\frac{5}{100}$ c.c. = $\frac{5}{10}$ mg. = $\frac{500}{1000}$ mg. = $\frac{1}{2}$ mg.
1½ c.c. = $\frac{7.5}{100}$ c.c. = $\frac{7.5}{10}$ mg. = $\frac{750}{1000}$ mg. = $\frac{3}{4}$ mg.
2 c.c. = $\frac{10}{100}$ c.c. = $\frac{10}{10}$ mg. = $\frac{1000}{1000}$ mg. = 1 mg.

(*f*) **Make up 50 cm. to 5 c.c. = 1·100**

Doses 1 c.c. = $\frac{5}{500}$ c.c. = $\frac{5}{10}$ mg. = $\frac{500}{1000}$ mg. = $\frac{1}{2}$ mg.
1½ c.c. = $\frac{7.5}{500}$ c.c. = $\frac{7.5}{10}$ mg. = $\frac{750}{1000}$ mg. = $\frac{3}{4}$ mg.

(*g*) **Make up 100 cm. ($\frac{1}{10}$ c.c.) to 5 c.c = 1·50**

Doses 1 c.c. = $\frac{5}{1000}$ c.c. = $\frac{5}{10}$ mg. = $\frac{500}{1000}$ mg. = $\frac{1}{2}$ mg.
1½ c.c. = $\frac{7.5}{1000}$ c.c. = $\frac{7.5}{10}$ mg. = $\frac{750}{1000}$ mg. = $\frac{3}{4}$ mg.

(*h*) **Make up 200 cm. ($\frac{1}{5}$ c.c.) to 5 c.c. = 1·25**

Doses 1 c.c. = $\frac{5}{2000}$ c.c. = $\frac{5}{10}$ mg. = $\frac{500}{1000}$ mg. = $\frac{1}{2}$ mg.
1½ c.c. = $\frac{7.5}{2000}$ c.c. = $\frac{7.5}{10}$ mg. = $\frac{750}{1000}$ mg. = $\frac{3}{4}$ mg.
2 c.c. = $\frac{10}{2000}$ c.c. = $\frac{10}{10}$ mg. = $\frac{1000}{1000}$ mg. = 1 mg.

(*i*) **Make up ½ c.c. to 5 c.c. = 1·10**

Doses 1 c.c. = $\frac{5}{50}$ c.c. = 1 mg.
1½ c.c. = $\frac{7.5}{50}$ c.c. = 1½ mg.

(*j*) **Make up 1 c.c. to 5 c.c. = 1·5**

Doses 1 c.c. = $\frac{5}{10}$ c.c. = 2 mg.
1½ c.c. = $\frac{7.5}{10}$ c.c. = 3 mg.

Note, in making up larger doses, that $\frac{1}{10}$ c.c. = 1 mg.

With regard to the preparation of tuberculin to be preferred I must speak with some reserve, for while I have had much experience in the use of the old I have necessarily had comparatively little of the new tuberculin. I am inclined to think, however, that the latter is the safer of the two, because, in appropriate doses, it produces much less reaction, but for that very reason it is not so reliable as the former as a diagnostic test; and a serious objection to the new tuberculin is its cost, particularly when the higher doses are reached, which precludes its use amongst the poor except in the case of those received into hospital. The initial dose of the old tuberculin is from half to one cubic centimetre of 1 in 1000, that of the new one cubic centimetre of 1 in 5000; while the final dose of the first is one cubic centimetre of 1 in 10, and of the second two cubic centimetres undiluted. Now the final full dose of the old tuberculin costs less than a penny, while that of the new is 17*s.*, so that it is mainly a luxury for the rich. It is to be hoped, however, that the time is not far distant when it may be obtained at moderate rates.

DIFFERENTIATION IN DIABETES.

BY F. W. PAVY, M.D. LOND., LL.D. GLASG., F.R.S.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

ONE of the most striking features belonging to diabetes is its varied character in different cases, and anything that will assist in distinguishing one variety of the disease from another affords help in throwing light upon the prospect that may be looked for. In connexion with prognosis, therefore, the differentiation of cases is a matter of deep importance.

It has long been known that there is a class of case in which the eliminated sugar is solely derived from the food. It constitutes what has been appropriately named the "*alimentary*" form of diabetes. Without any theoretical consideration being involved it may be simply said that the carbohydrate matter of the food fails to be dealt with in the system in such a way as to be placed in a proper position for utilisation. As a consequence it becomes discoverable as sugar in the circulation and is thence discharged as waste material with the urine. Under normal circumstances it is conceded that neither the blood nor the urine is sensibly influenced by the food looked at in relation to carbohydrate matter. No matter what the nature of the food, there is a certain small amount of sugar uniformly existing in the blood, just as there is in the various solid structures of the body, and, moreover, this, as the result of recent investigation, I have found[1] not to consist exclusively of dextrose, as was formerly supposed, but, as in the case of the other component parts of the body, of a mixture of dextrose with a lower cupric oxide reducing sugar.

In the "*alimentary*" form of diabetes the erroneous state observed in connexion with the urine consists purely and simply of the abnormal presence of dextrose. As a result, when the urine is examined quantitatively by cupric oxide reduction and the polarimeter the figures given by the two methods stand in accord, or sufficiently so for the difference noted to fall within the limits of error of observation. There is nothing present in the urine to make them stand otherwise. It will be easily understood that for the object under consideration great accuracy of examination is required and that expert hands are needed. As a further point in connexion with this kind of urine it is found that when the dextrose has been removed by fermentation with yeast, and Fehling's solution no longer gives any reaction, the polarimeter also fails to afford any evidence of either right-handed or left-handed optical activity. Simply placing the urine aside in a warm situation for 24 hours with some broken-up German yeast ordinarily suffices for the complete removal of the dextrose. Yet another point to be noticed is that the urine belonging to the "*alimentary*" form of diabetes does not possess the abnormality which leads to the production of a colour reaction with ferric chloride.

In contrast to this simple form of diabetes we have the class of affection in which the dextrose in the urine is derived from a twofold source. As in the "*alimentary*" form of the disease, dextrose is present as a result of faulty carbohydrate assimilation. In addition it is present as a consequence of abnormal proteid disintegration. By faulty metabolism a tissue breaking-down occurs, attended with the production of sugar associatedwith other abnormal degradation products. Through this proteid disintegration consequences arise which do not follow the simple faulty assimilation of carbohydrate matter. Pernicious results, it is true, ensue from the sugar that reaches the system from mal-assimilated carbohydrate matter, but further and graver effects arise from the condition attended with the production of sugar from faulty degradation metabolism. It is to the toxicity of one or more of these products of disintegration accompanying the sugar that diabetic coma is attributable. Thus a form of danger is engendered which does not attend the abnormal existence of the sugar alone.

In defining this class of case the term "*grave*" has been made use of. This term, it must be admitted, expresses the truth from its associated point of view; but from the conception it gives rise to it does not felicitously fit in with what is desirable for general medical use. It seems to me that the term "*composite*" strictly meets the circumstances in relation to the condition existing and also stands appropriately in contrast to the "*alimentary*" or simple form of the complaint. I propose, therefore, to use it to distinguish the form of diabetes in which evidence is presented of tissue disintegration constituting a partial source of the dextrose eliminated from that in which the eliminated dextrose is derived solely from the food. It is, then, the presence in the urine, concurrently with the sugar, of the products of faulty tissue breaking-down that characterises the "*composite*" form of the disease.

The normal ultimate products of disintegration resulting from the oxidation going on in the body are ammonia, carbon dioxide, and water. With the faulty disintegration occurring in the "*composite*" form of diabetes a series of products not recognisable in healthy urine become discoverable. The chain in its successive stages of descent runs as follows: β-oxybutyric acid, diacetic, often called aceto-acetic, acid, and acetone. It is true that a traceable amount of the last-named principle is susceptible of being found in normal urine. Such is not the case, however, with the others. From this it would appear that the kind of degradation is not absolutely foreign to the healthy state, but its extent of occurrence must be very insignificant. It should also be mentioned that there are certain other morbid conditions, apart from diabetes, in which the same set of principles are met with in the urine, so that the line of retrograde metamorphosis at the foundation of their production is not, strictly speaking, peculiar to diabetes.

As I have said, traces of acetone are met with in normal urine, but the presence of the other principles may be regarded as pathological. They are indicative of abnormal proteid destruction and their amount may be taken as furnishing a measure of the extent of its occurrence. This is

[1] Journal of Physiology, 1899, vol. xxiv., p. 479.

an important point, as we are thus enabled to read off in a given case the magnitude of the morbid action in play in the direction in question.

I will proceed to show the manner in which the estimation can be effected by methods adapted for clinical application. It may first of all be mentioned that oxybutyric acid is not found except in association with diacetic acid and acetone, but the last two may be present in the absence of the first. The same position exists with regard to diacetic acid and acetone. With diacetic acid there is a co-existence of acetone, but with acetone not necessarily a co-existence of diacetic acid. Indeed, what has been said about the normal state of things affords an exemplification of this. It seems as if the metamorphosis when occurring only to a small extent passes through to acetone without sufficient stoppage on the way to permit of the intermediate products reaching the urine. With an occurrence of the metamorphosis upon a larger scale, first diacetic acid and then both diacetic acid and oxybutyric acid become manifest.

It is the levo-rotatory β-oxybutyric acid that is found, and the effect of its presence is to neutralise, in proportion to its amount, the right-handed rotatory effect of dextrose. In the absence of oxybutyric acid the results given by estimation with cupric oxide reduction and the polarimeter should stand pretty closely in accord. It is to be understood that a certain amount of allowance, which should not exceed about one, or it may be from this to two, per 1000, must be made for a possible discordance occasioned by manipulative error. In the presence, on the other hand, of oxybutyric acid its levo-rotatory action takes away from the dextro-rotatory effect produced by dextrose and thus a reading is given it may be much below that which would have resulted if the dextrose had stood alone, and consequently correspondingly below the figures given by cupric oxide reduction. By the difference noticed an indication is afforded of the extent to which abnormal proteid disintegration is occurring.

Supplementary information is obtainable by fermenting the dextrose away and then examining with the polarimeter. When the urine is thus treated the yeast—German yeast obtainable from a baker is the best to employ—only affects the dextrose, and in a warm situation this principle is usually found to have disappeared in 24 hours. Testing with Fehling's solution should be resorted to to ascertain if complete disappearance has occurred. The optical activity of the oxybutyric acid being now allowed to come into unopposed play a left-handed rotatory effect is shown by the polarimeter standing proportionate to the amount that is present. As I have previously mentioned, the urine belonging to the purely "*alimentary*" form of diabetes is optically inactive after the removal of its dextrose by fermentation.

Diacetic acid is susceptible of recognition by a simple method of chemical testing. Gerhardt of Berlin noticed as far back as 1865 that in some cases of diabetes and not in others a wine-red colouration of varying degree of intensity was produced on treating the urine with ferric chloride. At first it was not known to what principle this result was attributable, but subsequently it was ascertained to be due to diacetic acid and the depth of colour produced serves as a measure of the amount present. From the facility with which the presence of diacetic acid is thus disclosed Gerhardt's reaction affords a ready means of revealing the abnormal proteid disintegration associated with the "*composite*" form of diabetes. The colouration is not absolutely distinctive, being open to production with more or less resemblance by agents reaching the system from an external source, but absence of colouration may be accepted as affording reliable information of a negative nature. The ferric chloride requires to be added till the precipitate of phosphate of iron that is first produced is redissolved or a slight excess may be added and the precipitate removed by filtration. No need exists to test for acetone. The presence of oxybutyric and diacetic acids suffices to render evident the morbid action that is going on.

I have been dealing thus far only with the non-nitrogenous principles derived from the abnormal proteid destruction that gives rise to a portion of the eliminated sugar in the "*composite*" form of diabetes. The matter, however, may also be looked at from the nitrogenous side of the disintegrating molecule by following the nitrogen to its exit with the urine. Under natural circumstances the quantity of ammonia, distinct from urea, eliminated by the kidney is quite small. It exists in combination with an acid and is reckoned to amount to about one gramme per diem on a meat, and to less than 0·5 gramme on a vegetable, diet. According to the view entertained by physiologists the nitrogen of the disintegrating proteid matter passes in the first instance into ammonia. This, as formed, combines with whatever acid is present to take it, and carbonic acid stands as the most notable. If the process of downward metamorphosis stopped here we should be having carbonate of ammonia conveyed in quantity to the kidney for elimination. Instead of so pungent and obnoxious an agent, however, being left by nature to be eliminated a further change ensues. By synthesis and dehydration the carbonate of ammonia becomes metamorphosed into the neutral and inactive principle urea, and the liver is the organ in which there are grounds for believing this synthetic process mainly occurs.

It is possible for some of the ammonia produced to enter into combination with an organic acid and still for the result that has been described to ensue. It happens in this way. Organic acids are susceptible of undergoing oxidation in the system. By this oxidation they give rise to carbonic acid which takes their place in combination with the ammonia and thus, secondarily, carbonate of ammonia is generated, which constitutes the forerunner of urea. In the case of mineral acids, however, the result is different. Should it happen that a mineral acid is present for the ammonia to attach itself to the combination fails to be in a position for the construction from it of urea; and, as a result, the ammonia passes undisturbed in its combined state into the urine instead of appearing there as urea. It is only the carbonate that can be synthesised into urea. The sulphate, phosphate, and chloride cannot be touched by the synthesising power, and such being the case ammonia escapes in proportion to the amount of available mineral acids present to combine with it and carry it off.

The fixed bases take precedence of ammonia in appropriating the mineral acids. Under ordinary circumstances the fixed bases and acids are so nearly balanced as to leave but little of the latter for entering into combination with ammonia, hence the small amount of ammonia finding its way into normal urine. With the active tissue breaking down occurring in the "*composite*" form of diabetes the sulphur and phosphorus of the disintegrating proteid becoming oxidised yield an extra amount of acid without a corresponding fixed base to combine with it. Hereby the conditions are supplied for the formation of an ammonia compound which passes in an unchanged state into the urine. It is in this way that the ammonia existing in the urine stands in relation to tissue disintegration. In fevers and other affections attended with increased tissue disintegration an increased amount of ammonia correspondingly appears in the urine.

It may be considered that the quantity of ammonia eliminated ought to be something under about one gramme per diem. More than this may be taken as meaning undue proteid disintegration, and in proportion to the extent of this disintegration the danger in diabetes increases of the occurrence of the coma belonging to the disease through the toxicity of one or other of the collateral products. Somewhat widely differing records of the amount of ammonia found to have been excreted by diabetics are given. Külz's [2] maximum observed is a little over nine grammes per diem; Rumpf [3] has noticed five, six, and seven grammes per diem; and Naunyn [4] says that the amount rarely exceeds seven grammes per diem and that whenever the quantity reaches four grammes his experience teaches him that coma sooner or later occurs. He refers to Stadelmann's record of 11 grammes as standing in quite an isolated position. Threatening coma, Naunyn asserts, may often be warded off by the free administration of carbonate of soda to counteract the effect of the augmented acidosis by the supply of a fixed alkali to meet the increased production of acid, but it has not been shown that any permanently beneficial result has issued.

No easy method adapted for ordinary clinical use exists, it must be said, for the quantitative determination of ammonia as a constituent of urine. One great obstacle is the facility with which ammonia is generated from urea. Although, therefore, applicable as a measure of tissue disintegration manipulative difficulties stand in the way, except with suitable laboratory provision, of obtaining the information that is wanted. This is no great loss, however, as what is needed

[2] Klinische Erfahrungen über Diabetes Mellitus, Jena, 1899, p. 408.
[3] Quoted from Külz, loc. cit., p. 394.
[4] Der Diabetes Melitus, in Nothnagel's Specielle Pathologie und Therapie, Wien, 1898, p. 297.

is obtainable through the chain of non-nitrogenous products that I have referred to.

Looking, then, at a case that may happen to be before us, means exist, without bringing in the question of ammonia, for diagnosing whether it belongs to the "*alimentary*" or whether it has advanced into the "*composite*" form of diabetes. Upon this point may hinge the view to be taken with regard to the future prospects of the patient, a matter that must be looked upon as of supreme importance. With the foundation I have supplied to work upon I will proceed to consider separately the two forms of the complaint and will, in the first place, speak of the "*alimentary*" class of case.

(To be continued.)

CONTRIBUTION TO OUR KNOWLEDGE OF URIC ACID SALTS.

BY F. W. TUNNICLIFFE, M.D., M.R.C.P. LOND.,
PROFESSOR OF MATERIA MEDICA AND PHARMACOLOGY IN KING'S COLLEGE, LONDON; ASSISTANT PHYSICIAN TO THE VICTORIA HOSPITAL FOR CHILDREN AND TO THE NORTH LONDON HOSPITAL FOR DISEASES OF THE CHEST;
AND
OTTO ROSENHEIM, PH.D., F.C.S.

IN chemical text-books two classes of uric acid ($\overline{U}$) salts are generally described—viz., the neutral ($(C_5H_2N_4O_3)$ M_2 or shortly $M_2\overline{U}$) and acid or biurates ($(C_5H_2N_4O_3)$ HM or $HM\overline{U}$).[1] We find, in addition to these in physiological and pathological works, a third class of urates mentioned, having the hypothetical composition of one molecule of biurate loosely combined with one molecule of uric acid, of the general formula $(C_5H_2N_4O_3$ HM). $(C_5H_4N_4O_3)$ or shortly $(MH\overline{U})$ $\overline{U}$. It is to this last-mentioned class of salts, the so-called quadriurates,[2] that we have more especially directed our attention. A very important rôle has been ascribed to these salts by Sir William Roberts who regarded them as being in a special sense the physiological salts of uric acid and as "constituting the only form in which uric acid subsists in the living body in the normal state."[3] Upon this assumption theories important both to the physiologist and physician have been built, but upon examining this subject critically it seemed to us that the actual existence of these salts was by no means established.

The quadriurate hypothesis rests upon results derived from the analysis of normal urinary deposits, and as these have further a wider physiological interest it seemed to us to be advisable to give shortly the history of the work previously done in this connexion.

HISTORY.

Berzelius was the first to observe the formation of crystals from amorphous urinary deposit under the influence of water.[4] These crystals he regarded as urate of ammonium. Heintz held the amorphous urinary deposit to consist of a mixture of the urates of ammonium, sodium, calcium, and occasionally potassium and magnesium.[5] He also pointed out that different sediments yielded different amounts of ash, varying from 2·98 to 8·02 per cent. He regarded the simultaneous precipitation of these three urates as the cause of their amorphous character and the calcium salt as an essential factor in the production of the same. Scherer, in criticising Heintz's paper, concludes that the sediment consists of a mixture of acid urates and free uric acid.[6] Lehmann confirmed the observation of Berzelius and identified the crystals set free by water as uric acid.[7] Scherer, in a later paper,[8] analysed four samples of urinary deposit and found that it was a complex mixture and that the amount of each of the bases and the sum of all of them were very variable. The next worker in this field was Bence Jones.[9] He analysed three urinary deposits obtaining different results in each case. He confirmed the important observation of Scherer in that he found in each sample the uric acid present in excess of the quantity required to form biurates with the bases. The excess of this non-combined uric acid was, however, not constant and in no apparent proportion to the amount of combined acid. The proportions were sample No. I. as 1 : 1·72; No. II. as 1 : 0·46; No. III. as 1 : 1·04. Although the proportions between the free and combined uric acids differed largely in the individual analyses it happened, by mere accident, that the average of free to combined in the three was as 1 : 1·1. Bence Jones subsequently proceeded to work out the proportion between the combined and free uric acid in the deposits analysed by Scherer. Viewed from this standpoint Scherer's figures gave discordant numbers, as follows:—Sample I., as 1 : 2·04; II., as 1 : 0·17; III., as 1 : 0·42; and IV., as 1 : 2·08. Bence Jones gives the average of these proportions as 1 : 1·1,[10] and does not seem to have attached any importance to this coincidence, but concludes: "It is very evident from these analyses that a mixture of different amounts of urates and uric acid constitutes the amorphous sediment of the urine." In spite of this, however, he seemed impressed that this proportion so "nearly approximated" (*sic*) to the "proportion hypothetically required by a salt whose molecule consisted of one molecule of uric acid combined with one molecule of acid urate." In pursuance of this idea he attempted to demonstrate the formation of such a salt under artificial conditions and succeeded in preparing compounds which were decomposed under the influence of water into biurate and uric acid. He produced, however, very slender evidence of the existence of a third class of uric acid salts, having the constitution of quadriurates, but in spite of this concludes "that quadriurates exist occasionally under natural conditions in amorphous urinary deposits, and can also be made artificially."

The subject remained in this condition until it was taken up by Sir William Roberts.[11] This observer, while acknowledging the inadequacy of the proof adduced by Bence Jones for the existence of quadriurates, endeavoured to prepare them himself by a modification of Bence Jones's methods. He was unable to demonstrate their presence in the natural amorphous urinary sediment but prepared amorphous urates, using human urine and various saline solutions as solvents for uric acid and to the compounds thus obtained ascribed the constitution of quadriurates. The analyses, however, upon which he relied as proving this composition are from the standpoint of the modern chemist inadequate, as will be shown later. Upon these insufficiently established data he proceeded to enunciate an elaborate hypothesis with regard to the presence and transformation of the so-called quadriurates in the tissues and blood. These views seem to have been more or less accepted and passed into many text-books,[12] although they have received no experimental confirmation.

The only experimental criticism which we have been able to find is by Pfeiffer.[13] This observer points out that the substances upon which Roberts founded his quadriurate theory were either sediments (and as such pathological) or of artificial origin, also that in the pathological sediments the presence of quadriurates could not be demonstrated. He himself further demonstrated the presence of phosphates in some of the so-called quadriurates prepared according to Roberts and pointed out that the quadriurates could only *ex hypothesi* exist in distinctly acid media, which condition does not obtain in the juices and secretions of the body except in the case of the urine and sweat. Minkowski[14] regards the assumption that uric acid exists in the blood in the form of a quadriurate as "unwarranted." In a recent

[1] This nomenclature is misleading in so far as the reactions actually exhibited by the salts in question do not correspond to it. The neutral salts react strongly alkaline and the so-called acid salts, which so far have been accredited with a neutral reaction, have an alkaline one (vide infra).

[2] In an earlier article on Piperidine as a Uric Acid Solvent (THE LANCET, July 23rd, 1898, p. 198) we mentioned that we had not been able to convince ourselves of the existence of the so-called quadriurates. This paper may be regarded as the outcome of further work in this direction.

monograph on uric acid[15] Schreiber questions the explanatory value of the quadriurate theory as far as concerns the phenomena of gout.

For the sake of clearness we purpose dividing this paper as follows: I. Examination of Sir William Roberts's chemical methods and critical repetition of his experiments. II. Natural and artificial urinary sediments. III. Decomposition by water of substances containing uric acid and urates, and new method of preparing them. IV. Physico-chemical observations on uric acid and its salts and the significance of the same. V. Conclusions.

I.

Sir William Roberts for the analysis of his so-called quadriurates relies upon the following method, which he terms "water-analysis."[16] The dry deposit was heated to about the boiling point with about 1000 times its weight of distilled water. The uric acid which crystallised out after 48 hours, was filtered off and weighed, the quantity remaining dissolved in the liquid being taken in regard. The filtrate which contained the biurate was decomposed with hydrochloric acid and the uric acid estimated as above. This procedure is open to the following objections. The estimation of uric acid by means of precipitation with hydrochloric acid (Heintz's method) is now obsolete, its inaccuracy and absolute unreliability for scientific purposes having been shown by many investigators.[17] The quantity of uric acid kept in solution and estimated at 0·0055 gramme per 100 cubic centimetres, although added to the free uric acid—the uric acid separated from the mixture of uric acid and biurate by water—does not seem to have been subtracted from the uric acid kept in solution as biurate. As the weight of substance in 100 cubic centimetres was 0·1 gramme, the error incurred amounts to 5·5 per cent. It is obvious that this error would affect seriously the amount of uric acid calculated as biurate. Further, Sir William Roberts seems to have overlooked the fact that all uric acid salts deposited from solution and dried at 36° C. (this being the case in his experiments) contain varying quantities of water constitutionally bound, amounting in the case of the magnesium salt to 35·9 per cent. The analyses made by the Croonian lecturer refer to substances dried at blood-heat, and therefore containing (*vide infra*) relatively high percentages of water. This fact, together with the errors of method mentioned above, seemed in our opinion to necessitate a repetition of his experiments.

We attempted to prepare so-called quadriurates by working under exactly the same conditions as Sir William Roberts, and obtained what, according to him, should correspond to a quadriurate of the following bases: sodium, potassium, ammonium, magnesium, and calcium. The substances were all dried at 36° C. and subsequently submitted to quantitative analysis, which consisted in estimating the amounts of water, bases, and uric acid. The water was estimated by drying at a temperature of 100° C. (if not otherwise stated) till the weight was constant. The bases were estimated in the usual manner. In order to obviate the errors by loss, &c., attendant upon the ordinary methods of uric acid estimation we determined its amount by nitrogen estimation (no other nitrogenous substances being present) and subsequent calculation. The nitrogen was estimated by Gunning's modification of Kjeldahl's method.[18] Each substance was examined microscopically with regard to the influence of water upon it.

SODIUM URATES.

According to Sir W. Roberts sodium quadriurate is formed from uric acid by the action of the acetates[19] and dimetallic phosphates[20] of this base. We prepared different samples by each method, using 3 per cent. and 5 per cent. solutions of the acetate of sodium, and 2 per cent. and 5 per cent. solutions of the phosphate.

A. Salts formed by the acetate method.—These salts were obtained in the following manner. The 3 per cent. and 5 per cent. solutions, as the case might be, were brought to the boiling point and then shaken up for a minute or so with an excess of uric acid, filtered hot, and the filtrate cooled rapidly on ice. A voluminous precipitate formed at once, the reaction of the liquid being slightly acid. The precipitate was filtered by the aid of a suction pump, washed with dilute and subsequently with absolute alcohol and ether and dried at blood temperature. These various manipulations were performed as quickly as possible. In the case of the 3 per cent. acetate solutions it was found that the water-free substances consisted almost entirely of uric acid. The first sample contained 99·41 per cent. uric acid to 0·59 per cent. sodium, the second sample contained 98·99 per cent. uric acid to 1·01 per cent. sodium. This fact has already been observed by Lipowitz who demonstrated *qualitatively* the nature of the precipitate.[21] In the case of the 5 per cent. acetate solutions the loss of water at 130° C. was estimated in the substance dried previously at 30° C. and found to be 8·08 per cent. (Table I.).

The "calculated composition" of the substance at 130° C. was arrived at by the following method of reasoning. 5·23 per cent. of sodium requires 38·20 per cent. of uric acid to form sodium biurate. If this quantity be subtracted from the total amount of uric acid (90·71 per cent.) the remainder (52·51 per cent.) represents the free uric acid. The amount of water lost at 130° C. (as well as retained at that temperature) is in molecular proportion to the sodium biurate corresponding to the sodium found. The same method of calculating was used in the following tables.

Another salt prepared in the same way with a 5 per cent. solution of acetate of sodium gave the following results (Table II.).

B. Salts formed by the phosphate method.—According to Sir William Roberts, "solutions of the common dimetallic phosphates of soda, &c., ... also take up uric acid very freely at blood heat, and the combination formed in this case in the first instance is likewise a quadriurate."[22] No analytical confirmation of this assumption is to be found. As Sir William Roberts does not give any directions as to the strength of the phosphate solution most suitable for this reaction we made some preliminary experiments on this point, using 1 per cent., 2 per cent., and 5 per cent. solutions. These solutions were treated with an excess of uric acid under constant agitation at blood heat for 20 minutes, filtered and cooled rapidly on ice. In the case of 1 per cent. solutions no immediate precipitation occurred, but took place on slightly acidifying with phosphoric acid, in which case the precipitate consisted of pure uric acid crystals. On another occasion a precipitate formed upon keeping the solution on ice for a considerable time without the addition of phosphoric acid. The precipitate showed under the microscope the characteristic uric acid crystals and was found upon analysis to consist to the extent of 97 per cent. of free uric acid. Similar observations have been made by Lipowitz[23] and especially by Liebig.[24] The latter regarded the phosphates as being the agents by which uric acid was kept in solution in the urine.

That pure uric acid is deposited if a solution of biurate of sodium, saturated at the body temperature, be mixed with a solution of monosodium phosphate and cooled, was shown by Voit and Hofmann[25] and confirmed by Bunge.[26] The conditions in their experiments are practically the same as those obtaining in our own, in which as the first products of interaction between uric acid and dimetallic phosphate, biurate and monometallic phosphate are formed, these latter reacting again as in the experiments of Voit and Hofmann and Bunge.

We next prepared urates of sodium by digesting 2 per cent. and 5 per cent. solutions of dimetallic sodium-phosphate with excess of uric acid at blood heat in the same way as before. The composition of the substances is shown in Table III.

From the above tables it is evident that neither by the acetate nor by the phosphate method could precipitates be obtained corresponding in composition to the hypothetical quadriurates. In the case of the phosphate method a fact of considerable interest is the constant presence of phosphoric acid in the urates formed. We were also able by the qualitative examination of many other similarly produced substances to demonstrate the presence of phosphoric acid whenever the precipitate was not entirely composed of uric acid. This latter fact, although evidently overlooked by Sir

Conclusions concerning the composition of substance dried at 36° C.				
3 per cent.			5 per cent.	
I.	II.	III.	I.	II.
The substance is nearly pure biurate of potassium, consisting of 3·85 per cent. uric acid and 96·15 per cent. of biurate, the latter holding 1 mol. H_2O constitutionally bound.	The substance is not a quadriurate, but a mixture of uric acid and biurate, the latter holding 3 mol. of water constitutionally bound.	The substance is pure potassium biurate, holding 1 mol. of water constitutionally bound.	The substance lost at 100° C. 3·36 per cent. of water, corresponding to 1 mol. of water calculated to the amount of KHŪ present. Found, 3·36 per cent.; calculated, 3·69 per cent. The substance is therefore a mixture of Ū and KHŪ, the latter holding 2 mol. of water.	The substance is not a quadriurate but a mixture of uric acid and biurate, the latter holding 3 mol. of water constitutionally bound.

William Roberts, was observed as early as 1844 by Golding-Bird[27] and independently by Pfeiffer,[28] who made some quantitative estimations.

POTASSIUM URATES.

The potassium salts were prepared in a manner analogous to the sodium compounds, potassium acetate being used. Two strengths of potassium acetate solutions were taken—namely, 3 per cent. and 5 per cent. The precipitates were filtered, washed, and dried in the usual way. The analytical results are expressed in Table IV.

From this table it is evident that in no case was a precipitate formed to which the constitution of potassium quadriurate could be ascribed.

AMMONIUM URATE.

According to Sir William Roberts a quadriurate of ammonia is obtained by the method described below.[29] The product, however, was not submitted to analysis nor was any further proof of its existence mentioned. Following the directions we prepared the hypothetical quadriurate as follows: 5 grammes of uric acid were boiled in a litre of a 1 per cent. solution of liquor ammoniæ. The solution was filtered hot and rapidly cooled on ice. An abundant stream of carbonic acid was then passed through it and the precipitate obtained was washed and dried in the usual way. All these manipulations were carried out as rapidly as possible. Table V. gives the result of the analysis.

TABLE V.—*Ammonium Salt.*

—	Analytical figures.	Calculated for ammonium biurate + 2 mol. H_2O.	Calculated for ammonium quadriurate.
Total uric acid ...	76·00 per cent.	76·02 per cent.	95·18 per cent.
Ammonia	8·27 ,,	7·69 ,,	4·82 ,,
Water	15·73 ,, (By difference.)	16·29 ,,	—

As will be seen from this table the salt dried at 36° C. is not a quadriurate, but ammonium biurate + $2H_2O$.

CALCIUM AND MAGNESIUM URATES.

According to Sir William Roberts the quadriurates of calcium and magnesium are prepared in the following manner.[30] The calcium salt is obtained by dissolving 0·5 gramme of uric acid in 100 cubic centimetres of cold lime water. To the filtered solution acetic acid was added, drop by drop, until neutralisation was approached. An abundant precipitate was then thrown down, which was caught on a filter, washed with rectified spirit, and dried. Magnesium quadriurate was prepared by digesting uric acid and calcined magnesia both in excess and distilled water at blood heat with frequent agitation for about ten minutes, the mixture was filtered warm, and the filtrate was rapidly cooled under a running tap of cold water. The precipitate was filtered, washed, and dried in the usual manner. In neither case is any analysis given in support of the supposed quadriurate composition of the respective product. We followed exactly Sir William Roberts's directions and prepared two samples of the magnesium and one of the calcium salt. Tables VI. and VII. express the results of the analyses.

TABLE VI.—*Magnesium Urates.*

—	Analytical results. I.	Analytical results. II.	Calculated for magnesium biurate + $12H_2O$.	Calculated for magnesium quadriurate.
	Per cent.	Per cent.	Per cent.	
Total uric acid ...	61·68	60·10	60·01	96·54
Magnesium ...	4·45	4·38	4·05	3·46
Water	33·87	35·52	35·94	—
	By difference.			

It will be seen from the above table that neither of these salts is a quadriurate and that whereas No. II. corresponds

$$\overline{U}$$

almost exactly to the formula $\overline{Mg}$ + $12H_2O$, No. I.

$$\overline{U}$$

approaches the required figures very nearly, containing only a slight excess of uric acid.

TABLE VII.—*Calcium Urate.*

—	Analytical results.	Calculated composition.		—
	Per cent.	Per cent.		
Total uric acid	76·51	—	—	The analysis of this salt shows that it consists of a mixture of uric acid and calcium biurate, the latter holding 14 mol. of water constitutionally bound. At 100° C. it lost 12·00 per cent. of water corresponding to 8 mol. of water calculated on the amount of biurate present. Calculated, 11·84 per cent.; found, 12·00 per cent.
Free uric acid	—	49·04	—	
Combined uric acid	—	27·47	30·47 per cent. calcium biurate require for 14 mol. H_2O	
Calcium ...	3·29	3·29		
Water ...	20·20	20·20	20·72.	

II.

NATURAL AND ARTIFICIAL URINARY SEDIMENTS.

So far as we are aware the only analyses approaching to completeness of naturally occurring urinary sediments are those made by Scherer and Bence Jones.[31] Since the number of these is somewhat scanty and the most recent was made in 1862 we thought it would be advisable to add to their number, especially as we had the opportunity of getting a constant supply of naturally-occurring deposit from the same person. The quantity necessary for analysis was collected in the following way. The urine directly upon being voided was rapidly cooled and the deposit allowed to settle. It was then filtered off by the aid of a suction pump, washed with alcohol and ether, and dried at 36°C. The fractions thus collected were mixed[32] together and kept in a stoppered bottle until sufficient for the purposes of analysis was obtained. The analysis gave the following results:—

Natural Urinary Sediment.

	Analytical numbers.		Calculated to water, &c., free substance.
Uric acid	73·40	.....	95·69
Ammonia	0·46	.....	0·59
Potassium	1·74	.....	2·26
Sodium	0·23	.....	0·29
Magnesium	0·06	.....	0·08
Calcium	0·34	.....	0·44
P_2O_5	0·48	.....	0·63
Water, colouring matter, and loss	23·29	.....	—

The amount of phosphoric acid present almost exactly corresponds to the amount required to satisfy the calcium (required for 0·63 per cent. phosphoric acid 0·53 per cent. calcium; found 0·44 per cent.). If the amount of uric acid be calculated which is required to form biurates with the remaining bases it will be found to be 19·33 per cent., this subtracted from the total uric acid leaves 76 36 per cent. free uric acid. It is therefore evident that the sediment in question consisted to a large extent of free uric acid mixed with the biurates of sodium, potassium, ammonium, and magnesium, and some phosphate of calcium. The proportion of combined to free uric acid is about : : 1 : 4.

With regard to the relative proportion of the different

[27] London Medical Gazette, 1844, p. 685.
[28] Loc. cit.
[29] Loc. cit., p. 27.
[30] Loc. cit., p. 27.
[31] Vide supra. These analyses seem to be unknown to Dr. Luff, who recently (Pathology and Treatment of Gout, London, 1898, p. 85) gives a partial analysis of a urinary sediment derived from febrile patients, which we shall consider later.
[32] Before adding each fraction, however, to the common stock it was examined microscopically with regard to its uniformity, absence of uric acid, or other crystals, and behaviour with water. If it showed any crystalline constituents (oxalates or phospates, &c.) or failed to give the formation of uric acid crystals upon the addition of water, it was rejected. It is interesting to note that each fraction weighed not more than 0·03 gramme, although originally it had a bulky appearance.

metals Table VIII. will be of interest as giving the result of all the analyses so far published in this connexion[33]:—

TABLE VIII.—*Relative Percentage Proportion of Metals in Natural Urinary Sediments.*

—	Authors'.	Scherer.				Bence Jones.			Luff.
		I.	II.	III.	IV.	I.	II.	III.	
Ammonium ...	18·33	42·26	70·73	70·47	42·26	24·20	37·29	20·45	46·0
Potassium ...	70·19	42·32	11·78	27·54	42·32	56·05	41·96	64·29	14·0
Sodium	9·00	11·41	17·49	1·69	11·41	19·75	20·75	15·26	40·0
Magnesium ...	2·48	—	—	—	—	—	—	—	—

It will be seen from the above table that the proportion of the metals varies in each case. Generally the amount of ammonium is very high. The two exceptions to this are our own analysis and Bence Jones's No. III., which latter also in the proportion of the other bases approaches most nearly to our own. The high ammonium percentage is probably to be explained by decomposition. The same irregularity as in the proportion of the different metals is also evident in the case of the free and combined uric acid (*vide supra*). Sir William Roberts[34] admits that his analysis, which was not published, of naturally occurring amorphous urinary sediments, gave results discordant with the quadriurate theory. This he explains by decomposition having taken place during the process of collection and to the fact that the sediments were derived from different urines. (In the case of the sediments collected and analysed by us these objections do not apply.) Nevertheless, he assumes that in perfectly natural urine and sediment uric acid exists in the form of a quadriurate. As proof of this he brings forward only *one* analysis of an *artificially prepared* sediment which he regards as the counterpart of the natural one. The process by which he obtained the sediment is essentially the same as the methods described above for the preparation of potassium and sodium quadriurate, except that urine was taken as a solvent instead of water. These experiments we repeated, following exactly Sir William Roberts's directions[35] (potassium acetate process). Two samples were prepared, different urine being used. Table IX. gives the results of the analysis:—

TABLE IX.—*Artificial Urinary Deposits.*

—	Analytical numbers.				Actual composition.		
	Lot I.		Lot II.		Lot I.		Lot II.
	—	Water-free.	—	Water-free.	—	—	—
Total uric acid	84·66	86·78	87·26	89·14	Free $\bar{U}$	17·47	10·17
Ammonium ...	0·33	0·34	3·98	4·53	$NH_4\bar{U}$	3·70	49·30
Potassium ...	9·33	9·56	3·48	3·96	$KH\bar{U}$	50·36	20·85
Sodium	3·24	3·39	2·07	2·34	$NaH\bar{U}$	28·00	19·41
Water, colouring matter, &c.	2·44	—	12·21	—	—	—	—

From this table it will be seen that the precipitate formed under the above conditions is not of constant composition (as is also the case in the normal sediments). The total quantity of the bases as well as their individual amounts vary within wide limits. Further, the quantity of free uric acid is also variable and in neither instance satisfies the quadriurate hypothesis. The relative percentage of the bases and the amounts of free and combined uric acid are given in Table X. The high proportion of potassium in the first analysis is explained by the fact that the urine, derived from the same subject as the urinary sediment analysed above, was originally rich in potassium, which was further increased by the method used (addition of potassium acetate). In the second analysis the urine originally was rich in ammonium.

[33] These figures are calculated from the analysis of the respective authors, with the exception of the last, which is simply copied.

[34] Loc. cit., p. 16.

[35] Loc. cit., p. 18.

TABLE X.—*Relative Percentage Proportion of Metals in Artificial Urinary Sediments.*

—	I.	II.
Ammonium	2·56	41·79
Potassium	71·93	36·53 parts per 100.
Sodium	25·51	21·68
Combined uric acid	69·31	78·97
Free uric acid	17·47	10·17

Luff, with the idea of supplementing Sir W. Roberts's analysis of artificial urinary sediment, estimated the metals in a mixed specimen of urinary sediment derived from fever patients. From his results (given above) he draws two definite conclusions. First, that generally the proportion of bases in urinary sediments is that found in his one analysis. This appears to us unjustified in the light of the analytical figures of other observers and our own results given above. Secondly, that the bases are present in the form of quadriurates. This conclusion is still more unjustified in that no estimation of the uric acid was made and thus no ground for his subsequent theoretical calculations exists.

III.

DECOMPOSITION BY WATER OF SUBSTANCES CONTAINING URIC ACID AND URATES AND NEW METHOD FOR PREPARING THEM.

We have mentioned the characteristic decomposition under the action of water of natural amorphous urinary sediment and the explanation given to this phenomenon by Bence Jones, and subsequently Sir W. Roberts upon the assumption of the existence of a true and definite chemical compound of biurate and uric acid (one molecule of each). Our own experiments have demonstrated that in naturally occurring and artificially prepared urinary sediments and urates the uric acid does not occur in this form, and hence that there is no ground for the quadriurate hypothesis. These substances, consisting of mixtures of uric acid and biurates, show under the influence of water the formation of uric acid crystals.[36] We shall in the future refer to them as decomposable urates.

The decomposition of these substances by water may best be seen under the microscope. For this purpose it is always advisable to have a relatively large quantity of water. If a very small quantity of the substance be intimately mixed with water on a slide and observed under the microscope, in a very short time the formation of transparent crystals will be seen. These crystals assume either ovoid or rectangular plate form, sometimes intermediate forms are observed, and occasionally the ovoid-shaped crystals pass completely into rectangular plates, probably owing to the influence of the dissolved biurate.

Since the substances showing this decomposition are mixtures of uric acid and biurate as shown by our preceding analyses, this reaction cannot be regarded as characteristic (and as such proving the presence) of quadriurates.[37] This being the case it should follow that any mixture consisting of biurate and uric acid should show this reaction which must be regarded as the dissolving out by water of the more soluble constituent, biurate, and the leaving behind of the less soluble one, uric acid.

That, however, another factor comes into play is evident from the following experiment. If a mixture in any proportion of finely powdered crystalline uric acid and crystalline biurate of sodium be treated with water under the microscope, the dissolving out of the biurate certainly takes place, but the uric acid remaining behind does not assume the characteristic crystalline form, shown by it when liberated from amorphous decomposable urates. It seems therefore that a necessary factor for this reaction is the presence of uric acid in an amorphous form. This obviously happens in the formation of the decomposable urates by the described methods in which an intimate mixture of uric acid and biurates, both in the amorphous

[36] Some of the naturally occurring amorphous urinary sediment examined by us, however, did not show this decomposition with water. This has been observed by Bence Jones and Pfeiffer. Some of the artificially prepared urates consisting as the analysis showed of nearly pure uric acid were also, from obvious reasons, not decomposed in this manner.

[37] Sir William Roberts frequently observed that substances not quadriurates showed nevertheless this reaction with water.

form, is precipitated from solutions by rapid cooling. If we examine more closely the *modus operandi* of this process we find that the first stage consists in the establishment of a state of equilibrium between the uric acid and the salt in question which gives rise to the formation of biurate in an amount proportional to the original contents of the solution in the salt; the second stage consists in the saturation of the liquid with uric acid. The amount of this substance taken up (apart from the ordinary physical conditions) depends on the quantity of the salt originally present in the solution. By varying the percentage of the salt corresponding amounts of biurate and uric acid are precipitated on cooling. The precipitate may thus range in composition from pure uric acid to pure biurate. From this it follows that it is possible to hit [38] by accident conditions which will produce a precipitate consisting of uric acid and biurate in equimolecular proportions—i.e., a so-called quadriurate. We succeeded in bringing further proof of the correctness of the above view by preparing decomposable urates by an original method. This consisted in taking solutions saturated at boiling point with biurate and treating the clear filtered solution with an excess of uric acid also at boiling point. Assuming the quadriurates to have the characteristics ascribed to them by Sir William Roberts this method of preparation necessarily excludes their formation in that they are, according to him, decomposed by boiling water. Upon cooling on ice the solution obtained above, an amorphous precipitate was formed which, after filtering, washing, drying, &c., in the usual way, showed under the microscope the characteristic decomposition. Two samples of the potassium compound prepared in this manner were submitted to analysis. The percentage results are shown in Table XI. :—

TABLE XI.—*Artificial Decomposable Potassium Urates.*

—	Analytical figures.		Calculated composition.			
	I.	II.	I.		II.	
	Dried at 130° C.	Dried in vac.				
Total uric acid	82·53	78·96	—	—	—	—
Free uric acid	—	—	30·53	—	31·40	—
Combined uric acid	—	—	52·00	KHU̅ 63·82 require for 1 mol. H_2O	47·56	KHU̅ 57·60 require for 2 mol. H_2O
Potassium ...	11·82	10·04	11·82		10·04	
Water	5·65	10·00	5·65	5·57	10·00	10·15
	By difference.					

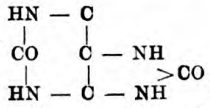
Sample I. was dried at 130° C. and lost at that temperature 11·00 per cent. of water. This amount corresponds to two molecules of water calculated to the biurate present (calculated 11·16 per cent.) The substance consists of a mixture of uric acid and potassium biurate, the latter holding three molecules of water. Sample II. was dried in vacuo and lost 5·20 per cent. of water corresponding to one molecule of water calculated to the amount of biurate present (calculated 5·12 per cent.). The substance therefore, as in the former case, was a mixture of uric acid and potassium biurate, the latter holding three molecules of water. It will be seen that the potassium biurate moiety of this mixture contains three molecules of water, loses one in vacuo, and one at 130° C. The last molecule is strongly bound, but appears to be slowly driven off at 150° C., at which temperature, however, the substance itself is partly decomposed, assuming a brownish tint. We also prepared the corresponding decomposable sodium urate,[39] the analysis of which is shown in Table XII.

[38] We presume this is what Sir William Roberts means by "a somewhat nice adjustment," p. 17, loc. cit.

[39] The exact procedure was as follows. Five grammes of crystallised sodium biurate were boiled with 600 cubic centimetres of water, filtered hot; the filtrate was boiled again with five grammes of uric acid. On cooling rapidly on ice a very small quantity of crystalline uric acid at first appeared, which was rapidly filtered off. The filtrate gave upon prolonged cooling an amorphous precipitate, which after being filtered and washed in the usual manner, gave the decomposition with water.

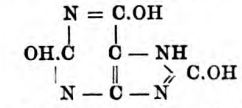
TABLE XII.—*Artificial Decomposable Sodium Urate.*

—	Analytical figures.	Calculated composition.	
Total uric acid	75·31 per cent.	—	—
Free uric acid	—	13·96 per cent.	—
Combined uric acid	—	61·35 ,,	69·75 per cent. require for 2½ mol. of water.
Sodium	8·40 per cent.	8·40 ,,	
Water	16·29 ,,	16·29 ,,	16·44 per cent.



The substance lost at 130° C., 9·80 per cent. of water, corresponding to one and a half molecules calculated to the amount of biurate present. The substance, therefore, is a mixture of uric acid and biurate of sodium, the latter holding two and a half molecules of water, of which one molecule is retained at 130° C.

From the preparation and analysis of the above substances it is obvious that artificial mixtures of uric acid and biurate may be obtained which are decomposable by water with the formation of uric acid crystals, and that therefore this behaviour does not prove the presence of a quadriurate.



IV.

PHYSICO-CHEMICAL OBSERVATIONS ON URIC ACID AND ITS SALTS AND THE SIGNIFICANCE OF THE SAME.

The now generally accepted constitutional formula of uric acid (first suggested by Medicus [40] and subsequently definitely established by the researches of E. Fischer [41]) is the following:—

Although this formula is in accordance with most of the reactions exhibited by this substance it does not provide an explanation of the existence of the now known six monomethyl-uric acids,[42] nor of its acid nature. A formula, however, fulfilling these requirements (as well as some others into which it is beside our purpose to enter here) is the following:—

which represents a tautomeric form of the acid. These two may be conveniently distinguished as the lactam and lactim formula respectively. According to Fischer the two substances corresponding to the above formulæ actually exist, the amorphous uric acid, as liberated from its salts in cold solution by acids, corresponding to the lactim form. This latter is distinguished from the crystalline form by its property of holding molecularly bound water. The crystals formed gradually from the amorphous acid, through the influence of water on standing, still contain two molecules of water according to the observations of Fritzche [43] and Matignon.[44] These transparent crystals probably represent an intermediary stage between the lactim and lactam forms, still containing two or one NC(OH) groups. By gentle heat, or on standing over sulphuric acid, they loose these two molecules of water and at the same time their transparency, being completely transformed into the lactam form.[45] It is the lactim form, however, which explains the salt-forming capacity of the acid.

The uric acids salts also occur in two distinct physical states, namely the amorphous and crystalline. We should explain this by assuming that these two forms are due to the presence of the tautomeric groups, the amorphous (iactim form) containing still two or one NC(OH) group, the crystalline (lactam form) containing only NH.CO groups.

[41] Bericht der Deutschen Chemischen Gesellschaft, vol. xvii., 1776, &c.

[42] Ibid., vol. xxxii., 2721.

[43] Journal für Praktischer Chemie, 17/56, 1839.

[44] Bulletin de la Société Chimique (3), 11, 571, 1894.

[45] A proof for the lactam formula of the crystalline uric acid might be seen in the behaviour of the dry substance with dry ammonia, under which conditions, owing to the absence of OH groups (according to this hypothesis), no salt is formed. Compare Bensch, Liebig's Annalen, 54, 201.

This assumption would explain the results of Baumgarten [46] who observed the transformation of the amorphous sodium biurate (precipitated from saturated solutions of sodium biurate by sodium phosphate or other salts) into the crystalline without any change of chemical composition, except the loss of half a molecule of water. We can confirm Baumgarten's observations in that we prepared sodium biurate in a different way, namely, by dissolving uric acid in weak (from ½ to 1 per cent.) solutions of sodium bicarbonate at boiling point. If such a solution be rapidly cooled amorphous sodium biurate is deposited (spheroids), on slowly cooling, however, the salt comes down in the crystalline form (needles). The former changes into the latter on standing or under the influence of water. Analysis of these two modifications showed that they were both pure biurate of sodium, the amorphous containing (air dry) two molecules the crystalline one and a half molecules of water. The existence of these two forms of urates, the transformation of the one into the other, and the above view with regard to their constitution may have an important chemico-pathological bearing. The extent to which the one must be regarded as physiological and the other as pathological, as well as the study of the conditions under which their transformation takes place in the liquids of the body, may obviously be of interest in gout so far as concerns the physico-chemical basis of this disease.

With regard to the state of uric acid and its salts in solution the following observations and remarks may be of interest. That uric acid is a very weak acid is known. Crystalline uric acid has no influence on moistened litmus paper in the cold. Hot saturated solutions of absolutely pure uric acid, however, show a distinct acid reaction with sensitive litmus and lacmoid. This is explained by the fact that in solutions the acid has the tautomeric form as described above. Uric acid being such a weak acid it is to be expected, according to modern physical chemistry, that its salts would be dissociated in solution. A qualitative proof of this would be that the solution showed an alkaline reaction. The neutral salts actually show a strongly alkaline reaction and are probably therefore dissociated in solution. Heretofore the so-called acid urates have been regarded as possessing a neutral reaction, probably upon the authority of Bentsch,[47] who first described and analysed them. We found, however, by carefully testing the reaction of solutions of these salts in an absolutely pure state with sensitive indicators that they reacted alkaline. The indicators we made use of were purified sensitive litmus, lacmoid, methyl-orange, Congo red, and rosolic acid. It was possible to show that for instance a solution of sodium biurate containing 1 in 100,000 reacted still distinctly with lacmoid, methyl-orange, and Congo red.[48] A further proof of the dissociation of these urates in dilute solution is the fact that the actual appearance of characteristic uric acid crystals can be observed under the microscope if pure acid urates of potassium or sodium, be treated with a large excess of water. This phenomenon is different from that exhibited by decomposable urates in so far as it requires a longer time—from half an hour to an hour. These observations require quantitative proof which would probably be afforded by the application of physico-chemical methods (molecular weight estimation in solution, &c.).

From what we have said above it follows that it is by no means necessary to assume that uric acid circulates in the fluids of the body as a urate, the small quantity present being probably hydrolytically dissociated. Other considerations have led O. Minkowski to hold a similar view.[49] This he expresses as follows: "After all we have no reason to assume that uric acid circulates in the blood as an alkaline compound."

V. CONCLUSIONS.

I. There is no evidence of the existence of a third order of uric acid salts—i.e., quadriurates—either in the artificial or natural amorphous urinary deposits or in the fluids of the body. Under these circumstances we regard it advisable to discontinue the use of the term "quadriurate."

II. The substances obtained artificially under the conditions supposed to produce quadriurates consist of mixtures in varying proportions of uric acid and biurates, or of pure uric acid or pure biurates alone.

III. Natural amorphous urinary deposits consist of a mixture of uric acid with urates of sodium, ammonium, potassium, calcium, and magnesium (containing in most cases in addition phosphoric acid).

IV. The property of some natural and artificial amorphous urates of showing the formation of uric acid crystals under the influence of water is due to the dissolving out of the more soluble biurate moiety and a change in physical state of the remaining uric acid.

V. Any theory concerning the pathology or treatment of gout or the uric acid diathesis built upon the assumption of the existence of quadriurates requires reconsideration.

VI. The existence of two forms of uric acid (the tautomeric lactam and lactim form) may explain the variation in the physical and physiological behaviour of this acid and its salts.

THE MANAGEMENT OF THE ANÆSTHETIC IN CASES IN WHICH RESPIRATORY IMPEDIMENT EXISTS.[1]

BY DUDLEY W. BUXTON, M.D., B.S., M.R.C.P. LOND.,
ANÆSTHETIST TO UNIVERSITY COLLEGE HOSPITAL.

IN bringing before this society a communication dealing with certain incidents in surgical anæsthesia I propose to group my remarks about certain cases taken from note-books. The cases which I have selected are those in which from various reasons either anatomical, pathological, or other, interference with respiration occurs. It is clear that if the obstruction exists at the time of giving the anæsthetic and gives evidence of its presence the anæsthetist is placed upon his guard. However, it often happens, as the sequel will show, that although such obstruction exists it does not reveal itself until the progress of anæsthesia introduces a new factor in the problem, while in other cases no obstruction exists as such until the anæsthetic itself leads to its production. All agree that do what we may sooner or later some of us are bound to meet with cases which present symptoms or phenomena in the progress of narcosis which confound our hard-and-fast rules while they jeopardise the lives of our patients. I have arranged some such cases and hope to reason out the causation of the difficulties which they present and to suggest how to obviate serious embarrassments.

As it is important to make my meaning clear it may be well to explain what should be understood by certain phrases. "Primary circulatory failure" may be taken to connote a depression of the circulation which is preceded by no interference with respiration. It is no doubt impossible, speaking physiologically, for any foreign gases or vapour to enter the blood through the epithelium of the lung cells without producing some influence—probably local—upon respiration. It is, I submit, quite possible for marked circulatory depression to arise without there being any apparent anterior respiratory changes of an injurious character. "Secondary circulatory failure" may be taken to mean a circulatory depression consequent upon and causally related to interference with the functions of respiration. It is the respiratory embarrassments which culminate in this secondary circulatory failure with which I propose, to-night, to deal.

There is, I take it, no doubt that the pulmonary circulation is materially assisted or hindered according as (1) the thoracic movements are maintained and are competent; and as (2) the gaseous composition of the blood passing along the veins and arteries of the pulmonary circulation is maintained at its physiological standard. The undue deprivation of oxygen and the excessive venosity of the blood do undoubtedly tell in the direction of impeding the pulmonary circulation and of hampering the efficient and effectual emptying of the heart. Obstruction to respiration may occur at various points and be due to various causes. Let us first consider those arising in the upper air passages. In some the cause is evident, it is well recognised and

[1] A paper read before the Harveian Society of London on May 17th, 1900.

easily detected and requires very little to be done in order to remedy it. In other cases this is not so.

Obstructed breathing due to blocking in the upper air passages commonly arises from enlarged tonsils with a partially occluded naso-pharynx, or from pharyngeal abscess, enlarged tongue, or old adhesions between the posterior wall of the pharynx and the tissues about the faucial arches. These cases may, in many instances, however, be extremely difficult to manage. Two cases I will mention as extreme examples of the condition. In both the patients were very young children and both presented extreme degrees of difficulty and danger.

CASE 1.—The patient was under three years of age and the tonsils were so large as to meet; they were inflamed and their surfaces were covered with glutinous mucus through which the air passed with difficulty. The child was being asphyxiated and tonsillotomy was determined upon as being necessary to give relief. As the little patient was very weakly and had to be in the sitting posture I gave him ether, keeping the mouth open throughout the inhalation. The choice of the anæsthetic was further made with the view of producing a very transient narcosis in case the protective effect of the reflexes was required. The operation was entirely successful and the ether did not add to the respiratory difficulties.

CASE 2.—In this case the child was aged two years and had had very frequent convulsions. The naso-pharynx was badly blocked by tonsils and growths and the little patient was liable to severe convulsive seizures at any moment. I gave the A.C.E. mixture at first until the child was dazed and subsequently ether and oxygen, with an excellent result. The removal of the obstruction had the most salutary effect upon the general condition of the patient.

There is a large group of cases in which difficulties arise through some mechanical interference with respiration. In these the use of anæsthetics may not be the actual cause, but it has the direct effect of intensifying the obstruction. Of these I have notes of many cases and I propose to read a few. The obstruction in some instances is not noticeable before the anæsthetic is commenced; of this class we have goitres without noticeable stridor and more especially in those cases in which the neck of the patient is short and thick and the tissues are hard and resistant. One sees the acme of this condition in the disease called angina Ludovici when the throat is surrounded by brawny hard structures which fix the jaw and practically render the trachea and larynx a rigid inelastic tube. In bad cases of lymphadenoma and lymphadenitis a similar necklet of dense tissues is met with. But it is by no means these obvious conditions themselves warning the anæsthetist of rocks ahead which alone are met with. It is frequently in thick-set plethoric persons whose chests are rendered more or less immobile by emphysema or fat that the greatest dangers arise. A typical instance of this occurred in my practice not long ago.

CASE 3.—The patient, a stout woman of between 40 and 50 years of age, was operated upon for mammary cancer. Beyond the fact that the patient had a short neck, high shoulders, and a slightly rigid chest there was no obvious reason for fearing difficulty. She had nitrous oxide gas followed by ether and she passed into the third degree of narcosis without much difficulty, although there was more duskiness than I liked. She was given air frequently and the head was kept high. The blueness increased without interference with chest movements or pulse. It was then found that owing to the rigidness of the muscles of her neck and jaws the chin could not be advanced nor could the mouth at first be opened. However, after some seconds the teeth were separated and the mouth was opened. The face was now purple and the signs of asphyxia were well marked. Rhythmic traction on the tongue was done and the surgeon was warned that laryngotomy might be required. He remarked that the operation would under the circumstances be well-nigh impossible. The tongue was swollen and all the faucial tissues were engorged. I passed my finger over the tongue and by hooking up its base with the epiglottis succeeded in starting respiration. As soon as air began to enter the chest the spasm passed slowly off in a few moments and the operation was continued and brought to a successful termination. The ether was replaced by chloroform which was not well taken. I kept a gag separating the jaws during the rest of the administration.

Two cases have been reported recently in which ether was given to patients with goitres and in both cases death from asphyxia resulted. I think when obvious impediment to respiration exists in the upper air passages, as in the case of goitrous persons, chloroform given from Junker's inhaler is far safer than ether, because when the patient under ether coughs or is salivated the cyanosed state is much aggravated. I cannot, however, disguise from myself that chloroform has its dangers in such cases and that if difficulties arise under its use the patient is placed in great jeopardy as the highly venous blood will certainly render him more receptive to a lethal dose. I have notes of cases belonging to this category in which the condition of obstruction occurred in the puffy venously congested tissues of chronic alcoholics. In such persons the respiratory difficulty is associated with two conditions equally difficult to relieve. In the first place most alcoholics have a badly acting heart; one believes the muscle to be degenerated and one knows that its rhythm is irregular and often chaotic. It is certainly, in most instances, extremely ill-equipped to do its work in the face of increased resistance, such increased resistance as arises when the pulmonary circulation is disorganised. But in the second place these patients are usually extremely restless and prone to muscular rigidity and clonus. I remember one instance which at the time caused me great anxiety and chagrin.

CASE 4.—The patient, an old man, had to undergo a rectal operation. He was sodden with drink, with puffy, swollen face and an extremely irregular, feeble heart, and all his tissues were engorged with blood. Under chloroform he struggled furiously and his condition was alarming while with ether the restlessness and the cyanosis were so excessive that it was with the greatest difficulty that he could be kept sufficiently still for the surgeon's purposes, and this in spite of the anæsthetic being given freely and care being taken to avoid asphyxial complications.

Of course, such cases are exceptional, but many occur which differ only in degree from those described. The practical lessons which these experiences have taught me may be summed up as follows. Every person must be treated as a problem, it may be put thus: Given the patient, find the best anæsthesia and the most suitable way of administering it. I am sure only experience can solve the problem. In cases of goitre I should in most cases regard chloroform as the safest anæsthetic. As the patient passes under its influence stridor usually becomes marked. This I believe arises from the fact that the trachea has lost much of its rigidity as a result of the pressure to which it has been subjected, and as soon as the muscles and intermuscular fasciæ become lax owing to the chloroform the support they usually give to the trachea is lost and so it collapses. Certainly in exophthalmic goitre, and to a less degree in other forms of thyroid disease, there is a great tendency to salivation and secretion of mucus, which under ether becomes so accentuated as to cause danger from blocking the bronchi and pulmonary alveoli. The importance of giving a minimal dose of an anæsthetic in these cases cannot be overestimated. When the patient has passed into the anæsthetic degree and the skin incision is made the chloroform should be given less freely although continuously. The method of giving chloroform intermittently is never advisable. It nearly always brings on vomiting and often dangerous faintness. The patient is for ever hovering between a condition of over-narcotisation and one of resumption of consciousness. It is one great advantage of inhalers such as Junker's over the open method that you can give chloroform in great dilution but maintain the continuity of the inhalation. With skill and judgment the drop-bottle method with a Schimmelbusch's mask will give a good result, but it is inferior to a regulating inhaler.

Posture, again, is one of our difficulties in surgical anæsthesia. It often happens in many operations that the position of election—namely, when the patient is lying on his back with his head turned to one side and slightly extended—cannot be adopted. In cases of laminectomy, in operations undertaken for the relief of empyema, in Estlander's operation, and in Kraske's operation for high removal of gut the patient is placed more or less on his face. Also in some gynæcological procedures when the semi-prone posture is adopted. I have found that when chloroform is given for these cases the hampered chest movements, especially when the patients are heavy and loosely knit, produce some cyanosis. In prolonged operations this may become very marked unless the precaution is taken to adapt the dose of the anæsthetic to the changed condition of the respiration. Nor can one, I think, wish for a

better guide than the rhythm and force of respiration in these cases. Provided the patient is completely anæsthetised before the change of posture is made it will be found that as the breathing becomes less deep and the rhythm is altered so will the patients require less and less anæsthetic to maintain them in a state of workable anæsthesia. Thus if one judges that the respiration is, say, of half the normal force half the normal dose of anæsthetic must be given, and so on. I have notes of several cases in which the thoracic movements were extremely slight owing to pathological pressure on the spinal cord high up.

CASE 5.—In this case it was found that even the most dilute vapour of chloroform produced such alarming respiratory symptoms that eventually I was obliged to desist. I tried several times giving a breath or two of the anæsthetic, working with an extremely low percentage vapour of chloroform, but on each occasion the same procession of events occurred and the respiration stopped. There was in this case a high lesion of the spinal cord, and no thoracic movements were made as the intercostal muscles were paralysed, and the diaphragm being also unable to act the breathing, such as it was, was maintained solely by abdominal movements. As soon as the chloroform began to act even these movements were checked with the above result. I tried in this case a method which I have subsequently always adopted. Oxygen is given freely coincidently with chloroform, and the chloroform vapour or the oxygen is pushed according to the requirements of the case.

CASE 6.—In a case similar to the last a man, about 30 years of age, suffering from a growth pressing upon the cord with almost complete respiratory paralysis, was seen by me in consultation to determine whether in his case an anæsthetic could be given without seriously endangering his life. I decided that it could, and accordingly I gave him oxygen with chloroform with the best result. I administered oxygen continuously and exhibited chloroform from my modified form of Junker's inhaler.

In operations on the thorax the obstruction to respiration is of another kind than those mentioned above. In these cases it often happens that there is "one lung" respiration, a condition which renders the patient more liable to danger from obstructive causes, either pre-existing or developed during operation. When the lung or lungs contain large quantities of pus and when this is associated with severe spasmodic cough the most alarming dyspnœa will often develop as soon as the patient becomes anæsthetic. The cause of this dyspnœa is probably the accumulation of thick muco-pus in the larger bronchial tubes which instead of being expectorated is aspirated back into the pulmonary alveoli. It is essential in all cases of thoracic operations when the abscess or source of the pus communicates with a bronchus that the patient should be anæsthetised to the second degree of narcosis only. This ensures analgesia without establishing abeyance of the protective reflex of coughing. A deeper narcosis is fraught with the gravest danger. The dyspnœa in these cases is further due to irritation of the over-sensitive mucous membrane of the air passages and this makes it extremely important that a judicious choice of the anæsthetic should be made. In cases of empyema, bronchiectasis, and pulmonary abscess with free expectoration I have found that even the purest ether given with the utmost care will provoke much cough and distressing dyspnœa. Chloroform usually is well tolerated if it is given with extreme dilution and slowly. The irritation and danger of giving ether in some lung cases are evidenced in the following case.

CASE 7.—A boy, aged about 10 years, suffering from empyema and copious expectoration, was given ether by the rectum by me. He went under quietly, but as soon as the absorption from the bowel became rapid he grew very dyspnœic and cyanosed. He was at once inverted, the anæsthetic was stopped, and the sound lung was compressed. A considerable quantity of pus escaped from his mouth and the danger was passed.

The case just given occurred some years ago when I had not realised the necessity in using rectal etherisation in thoracic cases to limit the narcosis far short of surgical anæsthesia. The main danger of these cases after that just described is undoubtedly connected with the change of position of the patient resorted to by the surgeon to enable him to complete his manipulations. It must always be remembered that during consciousness the patient's experience prompts him to adopt the position of maximum ease of respiration and this posture should as far as possible be maintained throughout the anæsthesia. If the body is suddenly turned towards the side of the healthy lung there is danger that the pus accumulated in the diseased lung during the anæsthesia will flow across and seriously interfere with respiration. Even when this does not take place I have repeatedly seen faintness and threatened syncope occur when the patient is rolled over towards the sound side. These dangers are increased where there is any extreme degree of cardiac displacement.

The violent cough and suffocative state which in my experience nearly always accompany any extensive opening into the pleura constitute a further danger and one which may prove fatal if the anæsthesia has been allowed to become at all profound. While speaking of perils occurring during anæsthetising in thoracic operations I would mention the danger in these cases of performing Silvester's method of artificial respiration should breathing fail. In a number of instances published in the journals in which this restorative measure was recorded as having been adopted a fatal conclusion to the case occurred. A moment's consideration will show that the effect of this method must be to pump the pus and mucus into the trachea and the mouth and then to aspirate it back again into both lungs alike, leading to the effectual crippling of the sound lung. It is safe to compress antero-posteriorly the sound lung, but it is safer to perform forced respiration of oxygen by a pair of bellows or Fell's apparatus.

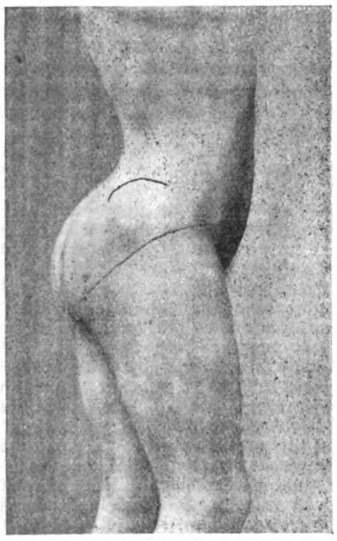
In summing up the teaching which the cases cited afford I think that the following propositions are worth tabulation. 1. The individual patient possesses a certain respiratory power. Individuals differ enormously in this respect, and it is the business of the anæsthetist to make himself acquainted with what I may perhaps be permitted to term the "personal respiratory equation of the patient." 2. This individual power of respiration is interfered with by every form of anæsthetic, more by some than by others, but under any anæsthetic the power of inspiration and expiration is lessened and in some cases to a very marked degree. 3. This lessened respiratory power may be of little or no consequence under normal conditions, but it becomes a factor of grave danger should any intercurrent cause of respiratory obstruction occur. For example, a delicate child breathing with difficulty through a blocked naso-pharynx is placed profoundly under chloroform. The mouth is opened and the jaw is depressed while the tongue is forced back. The respiratory power would under these circumstances be wholly inadequate to overcome the increased difficulties of respiration. The child would die and the death would be put down to heart failure, and the same occurs in cases of goitre, of malposition of the patient's body, of thoracic operation, &c. Thus it appears that all the cases cited fall into line and reveal to us not only the evident, but also the insidious, dangers associated with them. The object which I had in view in bringing this group of cases before you was to point out these dangers and to suggest the remedies and precautions appropriate to them.

Mortimer-street, W.

BILATERAL DISLOCATION OF THE HIP, PRESUMABLY CONGENITAL.

BY THOMAS PHILIP COWEN, M.D., B.S. LOND.,
ASSISTANT MEDICAL OFFICER TO THE COUNTY ASYLUM, PRESTWICH, MANCHESTER.

THE patient, a man, aged 30 years, suffering from mania with incoherence, was found on admission to the Lancashire County Asylum, Prestwich, to have an old dorsal dislocation of both hip-joints. His friends said that they were positive that the deformity was caused by injury at about the age of seven years and they asserted that there was not the slightest deformity, limp, or difficulty in walking before this. The injury referred to was a most severe thrashing inflicted by a drunken man over the back and hips accompanied with other violence. There was a marked deformity of both hips, but especially of the right. The figures (from photographs) show the condition well. The



head of the femur on each side was displaced upwards on to the dorsum and was fixed on the dorsum ilii by apparently a newly formed capsule in a position above and behind the acetabulum. When the patient stood easily there were some flexion and slight internal rotation of the thighs on the pelvis. There was considerable shortening of both thighs especially marked on the right side. An extreme degree of lordosis was apparent when an attempt to extend fully the legs was made. The apparent width of the hips was great so as to simulate a pelvis of the female type. The trochanters were displaced upwards and forwards so as to be nearer to the anterior superior spines than normally. The top of the great trochanter on the left side was two inches above Nélaton's line. The top of the right great trochanter was fully three and a quarter inches above Nélaton's line (Fig. 2). There was a slight downward tilting of the pelvis on the right side. Although there was some interference with the mobility of the thighs in all directions yet within a slight range of amplitude all movements were remarkably free, eversion and rotation out being especially so. Extension of the legs by forcible traction caused no alteration of the position of the trochanters so that the heads of the femora must have been fixed by newly formed ligamentous bands in their new positions. The patient could walk easily for fairly long distances even for several miles without great fatigue; he could run at a very good pace and could jump to a height of 18 inches with great facility. Progression was accompanied by a marked rolling waddling gait. He presented no other congenital deformities nor was there any history of similar affections in the other members of his family.

FIG. 1.

Congenital dislocation of the hip.

FIG. 2.

Congenital dislocation of the hip showing position of trochanter as regards Nélaton's line.

The illustrations show the condition very well. Nélaton's line was carefully marked in ink on the skin and also the line showing the position of the top of the great trochanter before the photograph was taken. There were no scars of injury or disease about the hips. Whether the deformity was due to a congenital malposition or to a traumatic dislocation is doubtful, but I am inclined to consider the case one of congenital dislocation of the hip in spite of the positive statements of the friends as to the history of causative injury. I think that the rolling shambling gait was probably thought little of until the immediate results of the injury drew special attention to it and the parts concerned. Yet, on the other hand, it is just possible that the cause may be a traumatic one as insisted upon, and it is rather on this account that I have ventured to regard the case as one of sufficient interest to be recorded.

Manchester.

THREE CASES OF PUERPERAL ECLAMPSIA.

BY FREDERICK SPURR, L.S.A. LOND.,
HONORARY DISTRICT SURGEON TO THE ROYAL MATERNITY CHARITY.

PUERPERAL eclampsia is described by Playfair as "one of the most formidable diseases with which the obstetrician has to cope," and he adds: "The attack is often so sudden and unexpected, so terrible in its nature, and attended with such serious danger both to the mother and the child, that the disease has attracted much attention." Those practitioners who have been called upon to treat this disease—fortunately a rare complication of pregnancy and parturition—will quite agree as to its formidable nature. The repeated attacks of convulsions are most distressing to witness and the patient's condition rapidly becomes so serious as to cause the gravest anxiety on the part of her medical attendant and friends.

The three cases now recorded occurred in my own practice in the course of a single year, and it may be noted as one of those coincidences so frequently occurring in medical work that they should follow one another at such short intervals, especially as in my previous midwifery practice, extending to some hundreds of cases, I had only met with one case previously and that nearly 10 years ago.

CASE 1.—On July 12th, 1898, I was called to a woman, 19 years of age, who had been attended by a midwife and had been delivered of a full-time female child at about 6.30 A.M. Upon my arrival I found the patient, a slightly built, dark-complexioned, and anæmic-looking woman, suffering from well-marked eclamptic convulsions. From her friends I learnt that it was her first confinement. Her previous health had been good, she had never suffered from fits of any kind, and she had kept about and at work uncomplainingly up to the commencement of labour, which had been easy and rapid. The midwife told me that during the labour she had noticed the patient's hands and face twitching and that she had at times appeared to be in a half-dazed condition. The first

actual fit came on at about 7.30 A.M., an hour after the completion of labour, and she had had seven or eight attacks before I saw her. On examination I found her in a condition of deep coma. The temperature was 101·5° F. and the pulse was 140. The pupils were widely dilated and equal, and they reacted but slightly to light. The urine on subsequent examination was found to contain a large quantity—about one-third—of albumin. The convulsions were typical eclamptic seizures and were recurring with alarming frequency. The clonic stage was protracted and the movements were general and violent, though invariably commencing in the left hand and arm. There was marked opisthotonos. The intervals between the attacks were of short duration, and in the words of her friends, "she only came out of one fit to go into another." Even during the moments of immunity there were spasmodic movements of the limbs, twitchings of the mouth, and rolling of the eyes. I gave the patient a five-grain dose of calomel, followed by a draught containing 40 grains each of chloral hydrate and bromide of sodium with digitalis. This had a marked beneficial effect, as the patient became much quieter, and from 9 A M. (when the draught was given) till 11 A.M. she had only four fits. At 11 A.M. I gave a hypodermic injection of one-fifth of a grain of pilocarpine nitrate. On visiting the patient again at 12.15 P.M. I was informed that the convulsions had again become more frequent and of longer duration. There had been five attacks in less than an hour, each one lasting four or five minutes, and as the patient had three severe attacks in quick succession shortly after my arrival I decided to give chloroform immediately. At first the attacks appeared to be rather excited than otherwise, and I found it necessary to "push" the administration of the drug almost to the full surgical extent in order to obtain any effective control of the paroxysms. For over an hour I kept the patient deeply under the anæsthetic, as I found that there was almost immediate recurrence of the convulsions on diminishing the strength of the vapour. Very gradually, however, after the first hour I was able to decrease the dose of chloroform and finally found it sufficient to give it intermittently, merely increasing the strength on any indication of commencing convulsions. The intervals of immunity became longer and longer and I discontinued the anæsthetic altogether three and a half hours after commencing its administration and when, with the smallest effective amount of chloroform, the patient had been half an hour without any signs of convulsive movements. After discontinuing the chloroform I remained for about an hour and a half by the bedside and noticed that as the effect of the anæsthetic passed off there was a return of the muscular twitchings, but they did not develop into an actual fit until just before I left, when there were three or four attacks of convulsions in quick succession, limited, however, to the left half of the body. I prescribed a mixture containing in each dose 20 grains each of chloral hydrate and bromide of sodium to be given every four hours so long as there was any continuance of the convulsions. The patient had the first dose about 6.30 P.M., and from this time till 9.30 P.M., when I saw her again, she had three fits. I gave her a second dose of the medicine before leaving and at midnight the nurse wrote to me a note to say that there had been no return of the convulsions and that the patient appeared to be sleeping quietly. During the early morning of the 13th there was some recurrence of the eclampsia, but as there were considerable intervals between the attacks, which were moreover of short duration, the nurse did not repeat the chloral draught. The patient remained unconscious during the whole day. She passed fæces and urine involuntarily seven or eight times. The pulse varied from 108 to 120, and the temperature, taken every four hours, fluctuated between 101° and 101·8° which was the highest point reached. There was no return of the convulsions and there were no muscular twitchings. On the 14th I found that the patient had had a good night, but she remained in the same unconscious condition as on the day before. The bowels were still loose and several involuntary motions were passed. The temperature during the day remained about 100°, the highest point reached being 100·4°. In the early evening the patient opened her eyes several times and looked about her, but did not take any notice when spoken to until near midnight when she gave several monosyllabic replies to questions. On the 15th the patient was able to converse freely. She remembered nothing of her confinement or subsequent illness, but complained of feeling stiff and sore all over "as if she had been beaten." The temperature and pulse were normal. The urine still contained a trace of albumin. From this time she made an uninterrupted recovery, but she had no memory for any events later than noon of the 11th, the day previous to her confinement, and she could recollect nothing of her labour or of the birth of her child, so that she was practically in a state of unconsciousness for three and a half days, during which time she gave birth to her child and had from 45 to 50 attacks of eclamptic convulsions with no subsequent recollection of pain or suffering.

CASE 2.—I was called to this case on Feb. 9th, 1899, at about 5 P.M., but owing to a mistake in the address which was sent to me there was some delay in my seeing the patient who had been attended by a midwife and had been delivered of a full-time child at about 4 P.M. On my arrival, at about 6 o'clock, I found the patient, a robust-looking, muscular primipara, 22 years of age, suffering from severe eclampsia, the fits occurring with such frequency as to seem almost continuous. Her temperature rose to 102 4° F. and the pulse was 130. The urine was normal in every respect and repeated examinations subsequently failed to show the presence of even the least trace of albumin. The midwife told me that the patient had a "slight fit" about a quarter of an hour before the birth of the child, but she noticed nothing else abnormal until about an hour after the completion of labour, when the fits came on in alarming frequency and severity and I was sent for immediately. The friends informed me that the woman had always been healthy and had never suffered previously from convulsions or fits of any kind. I gave her a two-minim dose of croton oil, followed by a draught of chloral hydrate and bromide of sodium (40 grains each) as in the previous case and saw her again at 7.30 P.M., when I found that the bowels had acted freely several times, but the convulsions were not diminishing either in frequency or severity. Under these circumstances I decided to resort again to the administration of chloroform which had been of such material service in my previous case. The attacks were more rapidly controlled by the anæsthetic in this case than in Case 1, but I again found that at first they appeared to be aggravated, and that it was necessary to "push" the drug in order to obtain efficient control of the paroxysms. In the present case I was able to discontinue the chloroform after a little over an hour and a half—i.e., at about 9.30 P.M. Between 9.30 P M. and midnight the patient had several fits, but they were not so severe or so prolonged as before giving the chloroform. I prescribed 15 grains each of chloral and bromide, to be given every three hours, if there was a recurrence of the convulsions. During the following day the patient remained unconscious. The temperature was never higher than 100·8°, and her pulse remained at 120. On the 11th I found her able to converse freely, but she remembered nothing of her illness or of the actual birth of the child, though she had a clear recollection of the earlier stages of the labour. She made an uninterrupted recovery except for a slight attack of bronchitis which came on towards the end of the week.

CASE 3.—This case was much less severe than either of the two cases above described—a circumstance which I attribute in great measure to the fact that the presence of albumin in the urine was detected and the morbid condition treated for some weeks before the actual confinement took place. The patient, a primipara, aged 23 years, came to me on April 1st, 1899, being then eight months pregnant, complaining of severe headaches, giddiness, and swelling of the feet and legs. She was suffering from great œdema of the legs and there was marked puffiness of the face. On examining the urine I found it loaded with albumin to the extent of nearly one half, and it also contained epithelial cells and tube casts. The patient had noticed the swelling of the feet and legs for quite a month before coming to me, but she did not seek advice until she was almost unable to walk and until the headache and other symptoms became severe. I strongly urged the advisability of inducing premature labour, but as neither the patient nor her husband would consent to this I was obliged to rely upon medicinal and dietetic treatment. I prescribed a mixture containing tincture of perchloride of iron, tincture of digitalis, and tincture of jaborandi, to be taken three times a day, and also 40 grains of compound powder of jalap to be taken every night for a week and after that every other night. At the same time I restricted her diet chiefly to milk and white fish. Under this treatment there was a

slight improvement. The albumin diminished in quantity, the headaches and giddiness were less severe, but the œdema increased until it extended to the vulva and the loins. On the 28th I advised copious daily enemata of soap-and-water and discontinued the jalap. Labour commenced on May 1st and the first stage lasted about 24 hours, the vertex presenting. About noon on the 2nd I ruptured the membranes and the head quickly descended on to the perineum, when the patient complained of great giddiness and shortly afterwards without any further warning became convulsed, the fit lasting several minutes. The child was born almost immediately afterwards and the placenta was expressed without difficulty. I gave her a draught containing liquid extract of ergot with 20 grains each of chloral hydrate and bromide of potassium. Half an hour after the birth of the child she had another attack of convulsions lasting for four or five minutes and followed by a short period of semi-consciousness and great exhaustion, the pulse going up to 140. When I left the house an hour later she had quite recovered consciousness and speech and had had no return of the convulsions, from which she did not subsequently suffer. A week afterwards the urine still contained a trace of albumin (about one-twelfth), and by the end of a fortnight it was normal. The œdema gradually disappeared concurrently with the disappearance of the albumin and the patient made an uneventful recovery, though she remained anæmic for some weeks.

With the exception of rupture of the uterus and concealed accidental hæmorrhage there is probably no more fatal complication met with in the practice of midwifery than eclampsia. Its serious nature, as well as its comparative rarity and its obscure pathology, have combined to invest this disease with such interest and importance that every case seems worthy of record. Many theories have been advanced from time to time as to the cause of the convulsions, but the etiology of the disease is still much disputed. There is general agreement amongst pathologists and obstetricians that it is due to a toxæmia, but while according to some authorities the origin of the toxin is to be found in some pathological condition of the placenta or the fœtus giving rise to bio-chemical changes, others deny the influence of either placental or fœtal conditions and maintain that it always arises from some morbid maternal state. Probably the most generally accepted view is that the disease "is due to a toxæmia of a urinary nature, toxic substances being retained in the blood which should have been excreted by the kidneys,"[1] and the frequent association of albuminuria with eclampsia certainly supports this theory. It has been stated[2] that one pregnant woman in 40 is albuminuric, and that of these one out of every four develops eclampsia; that eclampsia without albuminuria is of rare occurrence—one case in 10 cases. From these facts the practical conclusion is drawn that albuminuria should always be looked for in pregnant women, and actively treated during pregnancy when detected.

As regards treatment there can be no doubt that the chief indication is to eliminate the toxic matter from the circulation, or, failing this, to dilute it as much as possible. With this object in view purgatives, diuretics, and diaphoretics are given, and Dr. R. Jardine has recently strongly advocated the use of saline injections. In the two first cases above recorded I relied on calomel and croton oil respectively as purgatives, in each instance with very satisfactory results; but in any future case I should feel more inclined to resort to the more rapid and certain method of emptying the lower bowel with copious and repeated enemata. The second indication must be to counteract or modify the effects of the poison in the system, and for this purpose numerous drugs have been recommended—morphia, chloral hydrate, bromides, chloroform, veratrum viride, &c. After the experience gained in the three cases now described I should never hesitate to place entire reliance on the mixture of chloral hydrate and bromide, supplemented if need be by the prolonged administration of chloroform; but in a disease of such gravity, arising from a toxin, whatever its nature, of such virulence, it is absolutely necessary to give these counteracting drugs in full doses, and above all to persevere in the line of treatment adopted and that even in cases apparently hopeless.

A FEW CASES OF BRAIN INJURY CLINICALLY EXAMINED.

BY EDMUND E. DYER, M.B.EDIN.,
SURGEON TO CLACKMANNAN COUNTY HOSPITAL.

As the clinical study of head affections and injuries, when verified by post-mortem examination, is always interesting, the following cases may be of more than ordinary interest, more particularly as each of the following cases shows the enormous amount of brain tissue which may be destroyed without causing at least immediate death.

CASE 1.—The first case was that of a man, aged 20 years, who was admitted into the Clackmannan County Hospital suffering from a compound fracture of the skull which he sustained by being knocked down by the revolving handle of a steam winch. On admission his breathing was laboured and stertorous, there was considerable muscular twitching, and just after the accident he had had several violent convulsions. There was considerable hæmorrhage from the wound, which was about three inches above the left ear. He was insensible except to strong stimuli. There was a considerable scalp wound, with extreme shattering of bone which was also much depressed. I decided to trephine at once and having had the patient put under chloroform I removed entirely a triangular piece of bone measuring two inches by one and three-quarter inches by one and a quarter inches, and also two other pieces of small bone which had been crushed down from the inner table. The dura mater was to the naked eye apparently uninjured. As there was still a great deal of depression I inserted my finger between the dura mater and the frontal bone and lifted up the whole, when it went back into place with a snap. Immediately afterwards the breathing became regular and quite natural. The external wound, which was originally two and three-quarter inches in length, running upwards and backwards, and which was extended for operation to five inches, was closed, and a drainage tube was put in, which was taken out on the third day, the wound having practically healed without suppuration. The patient gradually recovered consciousness and on about the fifth day he was able to ask for anything. Curiously enough, from the day after the injury he insisted on getting out of bed for the purpose of passing urine, and this in spite of all attempts to prevent him. On the ninth day a reddish swelling and general puffiness developed over the nose and forehead which at first looked almost erysipelatous in character, and on the next day the temperature rose to 102·4° F. This, however, went down on the fourteenth day, when he gradually improved and spoke a little, and could answer questions if time was given to him, although cerebration was very slow. The improvement continued and on the seventeenth day he sat up in bed and ate a small piece of meat and complained that it was not enough. On the twenty-first day a swelling similar to that which developed on the forehead came on the posterior occipital parietal region. On the twenty-fourth day the patient developed extreme photophobia. He lay on his left side and curled himself up. He became comatose on the twenty-sixth day and died two days after, or 28 days after the injury. As the case fell under the scope of the Fatal Accidents Inquiry Act (Scotland), 1895, I made a post-mortem examination with a brother practitioner and we found the following conditions. The external wound was quite healed and the dura mater had thickened slightly at the point of injury. On reflecting the scalp the fracture was found to extend down to the left ear, right down to the left orbital plate, then right across the head posterior to the fronto-parietal suture to near the right ear. On lifting the skull-cap the dura mater was found to be adherent to it at the seat of injury. Below the dura mater the brain was found to be more or less covered with pus and immediately below the seat of injury was an abscess. The brain was removed and on making sections the abscess was found to extend from the point of injury, which was on the middle frontal convolution backwards and inwards, to the lateral ventricle. In the right cerebral hemisphere another abscess was found just below the surface of the brain at the angular convolution extending to a point close to the lateral ventricle

on that side. Pus was also found over the base of the brain and around the spinal cord.

In reviewing this case I can only suppose that the œdema over the frontal region was due to the abscess on the left side and that it went down with the contemporaneous fall of temperature when the tension was relieved by the pus bursting into the lateral ventricle. The second abscess did not find such exit. The other points to consider clinically in the case are the absence of paralysis, the extraordinary destruction of brain tissue, the extreme photophobia, and, finally, the length of time under the circumstances that the patient lived after the injury.

CASE 2.—The patient was an old soldier, aged 56 years, whom I admitted into the hospital suffering from right hemiplegia. The man had been ill for several days before his admission. No very definite history could be got. He was able to speak a few words, but cerebration was very slow, and on the left eye there were signs of an old keratitis. On the eighth day after his admission he became worse generally and he suddenly developed most violent convulsions which lasted for several hours, but which gradually subsided after treatment with heroic doses of chloral and morphia. From this date the convulsions never recurred, but there were slight twitchings from time to time. The patient died on the twenty-fourth day after his admission into the hospital and about the thirtieth day after the first seizure. Death occurred in the way so common with many of these cases except that the man took his nourishment well up to the day of his death. The temperature never rose above 99·8° F. There was no affection of the breathing.

The interest of this case lies chiefly in the post-mortem examination which, happily, I was able to make. On opening the head the dura mater was found to be adherent to the bone in patches all over the calvarium and was detached only with great difficulty in some places. The veins of the dura mater were enormously dilated. The whole brain tissue was extremely soft. On making sections of the brain horizontally the first thing which was discovered was a large round clot flattened from above downwards, measuring one and three-quarter inches in diameter, placed high up just inside the fissure of Rolando. On making further sections a well-organised smaller clot was found a little lower down just inside the middle frontal convolution, and again at a lower level a clot, of much the same size and character as the last, situate in the occipital region. These three clots were all found on the left side of the brain, but on making similar sections on the right side three other clots were found in almost exactly corresponding positions. The only difference was that the oldest clot of all—viz., the one in the frontal region—was here and the most recent clot of all was on this side in the occipital region. The last clot found was on the left side of the cerebellum and was three-quarters of an inch in diameter.

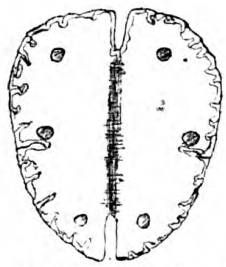

Diagram representing the relative position of clots in the brain in Case 2. Six clots are shown. The seventh clot was in the body of the cerebellum. The clots were not upon the same level, although diagrammatically they are so represented.

Now, which clot or clots, if any, caused the convulsions? From the date of the first symptoms and comparing the oldest clot with the more recent ones and considering the time which elapsed between the convulsions and the date of death I am inclined on these grounds alone to think it was the clot in the cerebellum. Although the age of the clot below the fissure of Rolando was much the same as that in the cerebellum, yet, on the other hand, the age of the corresponding clot below the fissure on the other side was distinctly different, and had this been the cause then it is reasonable to infer that instead of one set of general convulsions there would have been another at a later period, and this was not the case. The chief point of interest about this case is the number of separate hæmorrhages, no less than seven, each one being of a different age, and as far as affected the cerebrum almost exactly symmetrical; further, that so far as could be seen only one of these hæmorrhages caused the convulsions. The internal capsule was not affected and in no case apparently did the clot affect the grey matter of the brain. The man was an alcoholic and from the signs which were found I have little doubt that he had suffered from syphilis. In this case also there was no affection of the breathing.

CASE 3.—The third case is perhaps as interesting as the foregoing in showing an extensive destruction of brain tissue without a fatal ending. A lad was admitted into the hospital suffering from an injury to his head. It had been crushed from side to side between a fixed upright beam and the arm of a machine working horizontally, the point of which was as nearly as possible three-quarters of an inch square. On admission he was bleeding freely from a small cut over the right temple and a quarter of an inch behind the temporal artery. The injury to the bone was slightly to one side of the cut and to the front. I introduced a probe very gently and found a small fracture at the point indicated and with so much destruction of brain-tissue that the probe by its own weight entered exactly two and a half inches straight into the brain. Considering the condition of the patient and the absence of any urgent symptoms I did not think it a case for operation. The bleeding was stopped, an antiseptic pad put on, and the boy was sent to bed. The external wound, which was not sewn, healed without trouble and the patient was discharged in about three weeks. The boy after receiving the injury walked about 200 yards from the works to a medical man. But for a little faintness and pain for a few days the patient suffered no inconvenience. There was no rise of temperature or bad symptom.

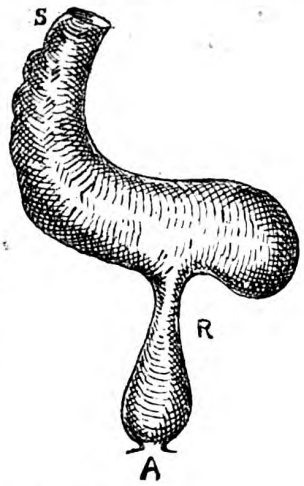
Each of these cases shows the enormous amount of brain-tissue which may be destroyed and, further, the extraordinary efforts the brain is capable of exerting to repair the damage, both effort and power being quite beyond what is often supposed it is capable of exerting.

Alloa, N.B.

SURGICAL ASPECTS OF CONSTIPATION.

BY S. L. WOOLMER, M.R.C.S. ENG.

THE following two cases are recorded in order to demonstrate what is believed to be a rare sequel to the most common morbid condition known to exist. I can find in no works on modern surgery any reference to a case of "aneurysmal" dilatation of the colon as the result of chronic constipation, and yet that it must exist in no small degree is very obvious. Due to this dilatation and the consequent accumulation of fæcal matter therein the condition of both patients was reduced to one of great gravity, as witnessed by the repeated attacks of intestinal obstruction, the degree of anæmia produced by insufficient alimentation, and stercorræmia. No enema could have possibly cleared the intestine nor could any procedure short of operation have relieved the patients.



CASE 1.—A man, aged 28 years, was under the care of Dr. Masi in the Military Hospital of Buenos Ayres. He had been constipated for four years. On Dec. 23rd, 1892, during a long march, and after a meal which consisted principally of cheese, he could obtain no movement of his bowels, and in this state he continued till March 12th, 1893, having only been able to expel by the rectum gases and a little blood. He then entered the Hospital San Roque in Buenos Ayres, where he was eventually relieved. From this period till November, 1896, he continued always constipated, relieving himself only by enemas and purges, and then with great difficulty. In November, 1896, he entered the military hospital under the care of Dr. Masi, where he recovered somewhat his functions by the application of abdominal massage and enemas of half a litre of olive oil administered daily. The presence now of blood in the motions and their ribbon-like character persuaded Dr. Masi that he had to deal with a malignant disease of the colon and he considered, therefore, the advisability of performing laparotomy.

Examination by the rectum revealed a very indistinct sensation of fulness behind the bladder, and by abdominal palpation nothing abnormal could be discovered. Laparotomy was performed on Feb. 2nd, 1897. The large intestine was found to be healthy from the cæcum to the sigmoid flexure, but on introducing the hand into the pelvis and behind the bladder a coil of intestine was felt dilated to the extent and form of a stomach. The bottom of this dilatation was occupied by soft fæcal matter. On lifting that part of the sigmoid flexure out of the abdomen which was adjacent to the tumour the latter was seen to accompany it, and on elevating its base it became immediately emptied, its contents falling into the rectum. The tumour was then easily brought out of the abdomen and was found to be the last part of the sigmoid flexure enormously dilated. Its surface presented striæ very like to those of the abdomen of a multiparous woman, and proof that it had been still even more dilated than at the time of the operation. On further examination it was found that movement of the bowels could only be produced when this cyst was completely full, and then only by regurgitation, as will be easily understood from the accompanying diagram (Fig. 1).

FIG. 1.

FIG. 2.

S, Sigmoid flexure. R, Rectum. A Anus.

An examination of this diagram will also explain the small calibre of the motions. The weight of the cyst full of fæcal matter must have produced such traction upon the sigmoid flexure that the orifice of communication with the rectum must have been obstructed almost completely and could only allow the passage of small flattened particles. The veins of the meso-sigmoid were immensely dilated, indicating the difficulty of the circulation and perfectly explaining the hæmorrhages which occurred before operation. The cyst once emptied was sutured to the abdominal wall in an elevated position by seven sutures with No. 0 silk, and the abdomen was closed. A dose of castor oil administered 36 hours after the operation relieved the patient of some tympanites and colic, and subsequently the bowels were moved once or twice a day abundantly, the motions being of normal calibre. On July 31st, 1897, the patient had no constipation.

CASE 2.—A man, 42 years of age, was admitted under my care to the sanatorium of Buenos Ayres on July 15th, 1897. He had suffered from constipation for some eight or 10 years, having become worse during the last 12 months. During this latter period his only food consisted of thin soup and light cocoa, due to a not unnatural desire to diminish as far as he was able the quantity of fæcal matter. In March, 1897, he had an attack of acute intestinal obstruction, but without vomiting; his tongue was dry and was covered with a brown fur and his countenance was anxious. On abdominal palpation a tumour was found in the hypogastrium, at the level of the insertion of the right rectus muscle; it was globular, smooth, and painless, and presented considerable resistance. By the rectum a tumour was also felt descending from above and reaching to the middle portion thereof, and by bi-palpation it was found to be identical with that felt through the abdomen. The finger could with firm and continued pressure be indented in the tumour, the indentation persisting afterwards. The tumour could not be dislocated from the pelvis.

Treatment by large enemas was adopted, the patient placing himself in the genu-pectoral position. Cascara sagrada was administered and periodically Hunyadi Janos water, and later an enema of olive oil was employed, with the effect only of enabling the patient to live in comfort, acute symptoms recurring if these measures were not adopted. But as a result of this treatment the tumour seemed to acquire greater mobility, at times abandoning completely the pelvis, as proved by rectal examination, and appearing high up in the hypogastrium and with marked and evident relief to the symptoms. Still the patient never had a comfortable movement of the bowels and never voided any fæcal matter, only what he termed "washings." Every week he had symptoms of acute obstruction and the diagnosis of pedunculated stercoraceous tumour of the sigmoid flexure appearing certain he was admitted to the sanatorium for operation, which was performed on July 19th.

On opening the abdomen the sigmoid flexure at once presented itself in the wound, enormously dilated, having lost completely its sacculated character. The small intestine was seen only once, and it appeared somewhat atrophied. On passing the hand into the pelvis it was found to be totally occupied by a large tumour which completely impeded the passage of the hand. The tumour was eventually lifted out of the pelvis by traction on the dilated colon, and it could then be "eased" out of its position. It was found to be a large "sessile" dilatation of the last portion of the sigmoid flexure (Fig. 2). Its peritoneal covering was quite normal, but it seemed to be somewhat thickened. No adhesions existed. The consistence of the tumour was solid, but by dint of force it could be indented by the finger. An effort was then made to reduce its contents into the rectum, but although moderate pressure was employed it was found impossible. One of two procedures was then left open—either to suture the elevated intestine to the abdominal wall or to incise it, liberate its contents, and return it again to the abdominal cavity. The former course was decided upon for the following reasons. The tendency of the tumour, due to its weight, was always to fall into the pelvic cavity, and I decided to marsupialise the tumour in the abdominal wound in the hope that the contained mass would tend to free itself gradually by reason of its own weight. In case this did not happen after adhesions had formed circumscribing the piece of gut left exposed in the wound it could always be incised later and the resulting fistula could be subsequently treated. Accordingly it was united to the central part of the abdominal incision by an uninterrupted suture, there remaining at the base of the wound a piece of the tumour of the size of a florin. The rest of the wound was then sutured in three places.

Recovery was uninterrupted after the operation and the patient expressed himself as being much relieved from the first. The bowels still only acted with enemas which brought away débris. On the eighth day it was noticed by rectal examination that the fæcal mass had fallen so as to be nearly within reach of the finger, and with a little trouble and by the aid of copious enemas and a long scoop it was completely removed. Its volume would be approximately three-quarters of a litre and it had lost entirely its fæcal odour. Up to August 10th the patient still only defecated by the aid of an enema, the motions being ill-formed but of distinct recent formation, and he could pass flatus with all facility. The tongue had completely cleaned by August 1st. The abdominal wound was therefore closed on the 3rd, local anæsthesia being produced by Schleich's infiltration process. During the following night the patient was much troubled by retention of flatus, which was relieved by the passage of a long tube up to the sigmoid flexure, and more completely later by the administration of an ounce of castor oil. On the 10th the wound had practically healed, and on this date the first natural and spontaneous movement of the bowels was produced. On the 31st the patient was discharged cured, having gained enormously in weight.

As I have before mentioned, although constipation is one of the commonest morbid conditions known, yet I can find no reference made by any author to the formation of a tumour such as that met with in the foregoing cases. Cahier in his monograph on Acute Intestinal Obstruction makes no mention of this condition, but Treves in his work on Intestinal Obstruction refers to tumours formed by the mass of

retained fæces, and observes that when they occur in the descending colon or sigmoid flexure they are divided into scybala, thus showing that in his vast experience he had probably never met with a case similar to those here recorded. He later mentions a very important sign in the differential diagnosis of these tumours—that is, that they are affected by pressure, yielding to the finger the sensation of a mass of dough or putty. In Case 2 this sign placed the diagnosis beyond a doubt, but it was inapplicable to Case 1 because no tumour could in this instance be felt.

It is noteworthy that in both cases the site of the tumour was the same—in the last portion of the sigmoid flexure, in a position where the external agency of the abdominal muscles is of little avail in the act of defecation. The impaction of fæcal masses in this region tends to produce dilatation behind it, and this distension may be localised or general. General dilatations are relatively common.

While the condition of the first case could only be accurately diagnosed at the time of the operation the great mobility of the tumour which subsequently developed itself in the second case gave rise to the belief that in this instance also would a "pedunculated" tumour be met with, for on various occasions it could be demonstrated bimanually that the lesser cavity of the pelvis was absolutely free, the tumour itself being felt well above the pelvis.

The second case illustrates also the inadvisability of the employment of Schleich's infiltration anæsthesia in any case where it is of prime importance that the eliminative functions of the bowels should be in a state of activity. The meteorism produced by the morphine in the injection caused great distress to the patient until it was relieved by the enemas and I shall certainly never employ it again in any laparotomy, where as a rule the master-key to success in after-treatment is so often found in a thorough movement and disinfection of the bowels.

My best thanks are due to Dr. Masi of Buenos Ayres for permission to report his case and for much valuable advice. At the present date (Nov. 10th, 1897) both patients are enjoying good health and are free from constipation.

Buenos Ayres.

FRACTURES OF THE INFERIOR MAXILLÆ TREATED BY A MODIFIED METHOD OF WIRE SUTURE AIDED BY THE ELECTRO-MOTOR.[1]

BY T. S. CARTER, L.D.S. R.C.S. ENG.,
HONORARY DENTAL SURGEON TO THE GENERAL INFIRMARY, LEEDS.

BEFORE describing wire-suturing it will be better for me to review briefly the whole subject of fractures of the inferior maxillæ and the treatment which has hitherto been usually adopted, in order that you may draw a comparison between what I trust I may call the old method and the new.

[Mr. Carter here referred to the frequency of fractures of the inferior maxilla and gave an account of their general features.]

Diagnosis.—The symptoms attending a fracture are, as a rule, clearly indicated. There are mobility, crepitus, and very often displacement, the teeth showing differences in level. Those adjacent to the fracture may have been loosened or knocked out and there will be pain and a good deal of salivation. Also the position of the patient is generally indicative as he will be found carefully nursing his jaw with one or both hands. If, however, there be any doubt it is well to grasp the jaw with both hands with the forefingers introduced into the mouth and crepitus between the fragments will be found and movement observable. Where the diagnosis is difficult, as in cases of fracture of the coronoid or condyloid process, it is well to push the index finger of the right hand well back into the mouth and by feeling at the same time externally with the left hand the fracture, if there be one, will be felt. A displaced fragment can often be pushed into its normal position in this way and retained by forcing the jaw upwards against the superior maxilla.

Treatment.—With reference to treatment of fractures, we may note that in early times if the patient got off with a united fracture and his life, no matter if the articulation was good, bad, or indifferent, he was thankful—a quiet thankfulness like that of the old woman who had only one tooth in each jaw and they were fortunately both on the same side. She said she had not had many blessings in this life, but she did thank God these two teeth touched each other. If in bygone days it was found that teeth by being out of position made the displacement more noticeable, the surgeon by means of forceps soon altered that state of things. The conditions which most favour a satisfactory result in these cases are as follows. The fractured ends of the bone should be firmly maintained in correct apposition after reduction of the displacement. The splint should not interfere with speech or movement of the jaw, or with a proper cleansing of the mouth. Also it is of all things important that we should be able to note throughout the treatment that the grinding surfaces of the teeth of one or both fragments oppose those of the other jaw. This should be the chief aim of the operator, as by its neglect a patient's future health may be imperilled owing to the loss of half his masticating power, and also his personal appearance may be considerably damaged.

It is not necessary for me more than to name some of the forms of splints most frequently used as they are all well described in surgical and dental works. They consist of the four-tailed bandage, and, amongst others, those called after the originators—viz., Kingsley's, Hern's, Gunning's, and Hammond's. Of all interdental splints I think, in cases where there are plenty of firm teeth standing, the latter is most useful on account of its simplicity. It has the advantage of allowing the mouth to be thoroughly cleansed and does not interfere with a full view of the fracture being obtained, nor does it interfere with free movement of the jaw. Samples of the splints I have named are before you, but they are but few of the many which have been devised. This shows the necessity for some simple universal method free from the one great objection—namely, that of having to make a special splint for each case. This is a tedious business, and when carried out you have in most cases filled the patient's mouth with a bulky mass interfering with speech, with proper cleansing of the oral cavity, have difficulty in observing the relative position of parts, and have succeeded in producing salivation and general discomfort to the patient. I therefore took up wire-suturing of the jaws, somewhat on the lines suggested by Dr. Buck of New York in 1847 and later, in 1863, by Mr. Hugh Thomas of Liverpool. The method adopted by the latter was to drill holes, one on either side of the fracture, and having passed his wire to coil it by twisting on a steel rod. I noted, however, in the record of his cases that he stated that the coils made had to be tightened every two or three days. This I take to be due to the coils rather untwisting. Instead of this method I bring the ends of the wire together and twist them and this brings and firmly binds the fractured ends of the bone equally in contact on both buccal and lingual surfaces. The twisted ends of the wire when bent flat, take up less room than the coils, which is an advantage. I notice in two of the cases recorded by Mr. Thomas and one by Mr. Rushton Parker of Liverpool that in order to get at the jaw beyond the angle of the mouth they drilled through the cheek and drew the wire into the mouth. If, however, a retractor be used, this plan is quite unnecessary.

When I first read the notes of these cases I was struck by the fact that to bore the holes by means of a gimlet or Archimedean drill was primitive. When therefore Mr. T. R. Jessop gave me my first jaw case, which was one of Syme's operation for removal of the tongue, followed by non-union at the symphysis, I determined to use the dental engine. With this object I had several long drills made with different-shaped cutting edges, and I found the bayonet shape the best. This was made to fit a dental engine and I had a thicker driving cord added and blocks of lead fixed to the fly-wheel to add to its power. Armed with this I approached the patient and drilled two holes through his jaw as readily as boring through chalk. I was pleased with the result at the time and with the success which followed in many cases afterwards. As, however, the use of the foot for treadle work is a trained movement not practised by surgeons I consulted Mr. S. W. Cuttriss, electrician, and induced him to bring out an electro-surgical motor primarily for the object of drilling any bone in the body, the removal of exostoses, and general aural work, and by degrees to develop it until it could be used for trephining and any form of bone-work. The motor is before you and is on the lines of

[1] A paper read before the British Dental Association at their annual meeting held at Leeds on June 2nd, 1900.

those made by Messrs. Cuttriss and Wallis for dental purposes, only more powerful. It may be constructed to work with either continuous or alternating current as required.

[Mr. Carter here gave an account of various points in the mechanism.]

To facilitate wire suturing I have devised a case containing in small compass all my instruments for suturing fractures, whether of maxillæ, patellæ, or long bones. It was described and illustrated in THE LANCET of August 27th, 1898, p. 558. My method of procedure in a jaw case is as follows. Having taken the necessary antiseptic precautions I take a piece of silver-plated copper wire No. 19 B. W. G. and for the distance of nearly an inch from the end file away half its thickness. To make it more ductile I then pass the wire slowly through the flame of a spirit lamp, making it a dull red for a length of about six inches. With the patient under ether I draw down the lip and with a sterilised bayonet-shaped drill in the motor bore a hole slowly through the jaw posterior to the fracture and between the fangs of the teeth. In this position the inferior dental nerve is avoided, and the opening should be made not less than a quarter of an inch from the fracture. While drilling with the right hand the spoon is held on the lingual side so as to guard the tongue from the point of the drill as it emerges from the foramen. Having withdrawn the drill the plated wire is pushed through from without and by means of forceps drawn well into the mouth. The difficulty has been in returning the silver wire, as it is not easy to find the return passage by simply probing for it. Having, however, drilled the hole on the other side of the fracture a pliable copper needle may be pushed through from without and bent at a suitable angle to allow of being readily threaded with the p'ated suture wire. Where the point of the wire has been filed it may be bent so as to form a hook, and if the needle is then withdrawn the wire will follow. It is well to drill the hole in the depressed portion of bone on a lower level than the other one, so that there may be a lifting tendency and greater resistance to a relapse in position. I make sure that there is no foreign body, such as a loose fang, between the broken ends of the bone and then lift the displaced portion into position, apply the key, and then twist the wires until the ends of the bone are drawn tightly together. To prevent the key from cutting the wire it is necessary not to push it nearer the bone than, say, half or three-quarters of an inch before the first turn is given. Having severed the twisted wire with side-cutters an end is left projecting about half an inch long. To prevent this from cutting the cheek I cover it with a short piece of indiarubber tubing of the calibre of a crow's quill and turn it down flat. It is well not to drill quickly, as I think the interesting little sequestrum which I will pass round will prove. I found it slung like a bead on the suture wire on the tongue side, as shown in the model of the mouth taken at the time. The hole through the centre was made by the drill and the necrosis was probably due to heat produced by the speed of the revolving engine-point; it is well, therefore, to observe caution in this respect, and also not to advance the drill too rapidly through the bone tissue.

Fractures of the ramus are uncommon, and when they do occur there is little displacement. For cases at the angle, however, where there may be some difficulty I am going to have a right-angle piece made to carry a drill of only just sufficient length to go through the thickness of the ramus and its coverings from the lingual side. In using it so far back it will be necessary to avoid the inferior dental nerve and to have the tongue drawn forward to prevent it from being pushed backwards over the glottis by the angle-piece. Where it is necessary to divide the lower maxilla, as in Syme's operation for removal of the tongue, it is advisable that the surgeon should make, not simply a vertical incision, but two oblique ones from above and below, meeting at an angle, so that the fragments may lock into each other and facilitate retention by wire suture in normal position. Until quite recently I used the dental engine for drilling purposes and I will briefly record four cases out of the many I have done. The models taken before and after treatment are before you.

CASE 1.—A powerful man, aged 19 years, was admitted to the Leeds Infirmary on May 11th, 1892, suffering from compound fracture of the lower jaw, and on May 19th I was asked to see the case. I found the lower maxilla fractured transversely across the ramus on the patient's left side, also perpendicularly between the two fangs of the first molar on the same side and likewise perpendicularly through the socket of the second bicuspid on the patient's right. The front portion was much displaced, being deeply depressed and exposing the second fang of the molar in its full length. The front portion was also considerably overlapping the posterior part, carrying the median line of the maxilla considerably over to the patient's left side. On May 20th I drilled holes through the jaw and wired in the manner described. There were no complications and on June 11th the teeth were all well opposed to each other and on July 7th I removed the suture and found all firm.[2]

[Details of two other cases were then given.]

CASE 4.—The patient was a canal boatman who during the early morning of Dec. 28th, 1896, was winding a lock windlass when his foot slipped on a piece of ice and the revolving handle struck him across the jaw, causing a double fracture of the inferior maxilla and more or less concussion of the brain. I found the jaw fractured through its body between the second bicuspid and first molar teeth on the left side, and between the first and second bicuspids on the right side. The anterior portion was much depressed, and although there was no external wound there was considerable swelling. On the 30th he was anæsthetised and I wire-sutured the parts together. On March 15th, 1897, I tightened the sutures and on May 7th I removed them. The fractured portions of the jaw were perfectly united and there was complete antagonism between the upper and lower dentures.

For suturing purposes I have always used annealed silver-plated copper wire, and that it is preferable to solid silver will be best illustrated by the following two cases and by the expert evidence which Professor John Goodman, M.I.C.E., of the Yorkshire College, has so kindly given.

I was asked to see two cases of fractured maxillæ admitted to the Leeds Infirmary on Feb. 9th and Feb. 20th last. The messages arrived, however, after I had left Leeds, and my method of wiring was adopted in both cases, the drilling being done by the electro-motor. Solid silver wire was used, however, and it broke on twisting. In the other case it broke three times during the twisting stage. Thinking it important for surgical work generally that it should be determined which kind of wire was the stronger and more ductile I brought the matter before Professor Goodman, whose tests proved as follows—that the number of twists per inch in length which annealed silver-plated copper wire would bear before fracture, was 22·8, as compared with 18 only in solid silver wire. When not annealed the difference was 13·7 as compared with 12·8. This proves that annealing greatly increases the ductility of wire. Testing the wires in pure tension it was found that the breaking load of copper as compared with silver was 47 pounds as compared with 42. The detailed results are as follows. Silver-plated copper wire: diameter, 0·041 inch; sectional area, 0·00132 square inch; breaking load, 47 pounds; breaking stress in pounds per square inch, 35,600; extension per cent. on three inches before fracture, 41·0 per cent. Silver wire: diameter, 0·040 inch; sectional area, 0·00126 square inch; breaking load, 42 pounds; breaking stress in pounds per square inch, 33,300; extension per cent. on three inches before fracture, 33·0 per cent.

From all this you will note that copper wire is both stronger and more ductile than silver. Also Professor Goodman states that if annealed copper wire be used it should, in his opinion, be annealed before plating, as a very slight amount of overheating causes the silver to scale off. For this reason, therefore, and in order to simplify matters, I have arranged with Messrs. S. Maw, Son, and Thompson to supply wire already annealed. Having wired the bones there are just two or three matters to see to. As nearly all cases of fractured jaws are compound, there is liability to sepsis and to obviate this the wound should be well irrigated and various forms of antiseptics used. It is also well to dust the wound with equal parts of iodoform and boric acid. Perfect rest must for a time be given by not allowing conversation which, as a muscular effort, disturbs the part in the early stages, and mastication must not be allowed for some weeks. Nourishment should be given in liquid form and this may well be done by fixing an indiarubber tube to the spout of a feeding-cup and then passing the tube into the mouth through the space left by the loss of a tooth. In these days of tooth degeneration we rarely find a set complete, but in

[2] THE LANCET, Dec. 3rd, 1892, p. 1256.

the improbable event of there being no such space the tube may be passed round the back of the last molar.

In concluding my paper I cannot do better than finish by stating that, judging from the long experience which I have had in the treatment of fractured maxillæ where there is displacement, the opinion I have come to is that for neatness, cleanliness, simplicity, and good results there is no better method than by wire suture. There is a claim on it, also, from a hospital point of view, as after, say, the second day, except in case of other injuries received, the patient is discharged as an in-patient. Also I believe that for surgical purposes there is a great future for the electro-motor, and that it will ultimately become an essential and invaluable aid in all complicated forms of bone-work.

It has often struck me in watching operations daily performed at the Leeds Infirmary that to open the mastoid cells by means of chisel and hammer, remove exostoses by aid of a gouge, trephine the skull by hand, drill holes through bone with gimlet or Archimedean drill, that the muscular effort required lessens the delicacy of touch so conducive to advanced work. Also in aural cases may not some cerebral irritation be induced? At present the use of the motor is limited, but there will be no difficulty in making it work perfectly an ordinary saw, drill, trephine, automatic chisel, and do any form of bone-work. In cases where electric power is not to be had either accumulated or otherwise, a spring motor might be made which would be of great service to our army surgeons in time of war. For it is important that advances made which benefit the patients in hospital should also be arranged to enable others not so situated to receive the same measure of benefit. I would suggest that the instrument be arranged to shut down into smaller space so as to be more portable. There should also be disconnecting gear in the handpiece so that if the operator lessens his grip the cutting instrument should immediately cease working, in the same way that you can by releasing a spring in the receiver of a telephone place it out of use. Of course, we must not expect that for philanthropic reasons alone electricians will bring about these changes. It will be a question of demand and supply, so that the producer may reap benefit from his efforts. We may rest assured, however, that in these days of scientific advancement our surgeons will not fail to take up anything which will better enable them to benefit their patients. In this way the demand will rise, and I fully believe that the time is not far distant when the surroundings of every surgeon will not be considered complete without an electro-motor.

Leeds.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

PYO-PNEUMOTHORAX DUE TO EMPYEMA PERFORATING THE LUNG; RECOVERY.

BY F. PERCY ELLIOTT, M.B., C.M. ABERD.

THE following case deserves to be recorded. The patient, who was a monthly nurse, aged 44 years, had up to this period of her life always enjoyed good health, having had nothing wrong with her beyond the usual ailments of childhood. She had never had bronchitis nor had she ever suffered from any chest affection previously. On her side of the family there had been no tendency to lung trouble. Her husband died from phthisis about three years before her illness and she carried out the duties of nurse, not only occupying the same room, but constantly sleeping with him down to nearly the end of his life. She had four children, all of whom exhibited a strumous taint. On Nov. 12th, 1894, while following her occupation, she suddenly experienced a sharp pain in the right breast which "caught" her on breathing. This was the first thing that led her to believe that something was wrong with her. She had neither any rigors nor any sensation of chilliness. In consequence of increasing pain she was forced to take to her bed. She at that time complained of pain in, and just below, the right breast, aggravated by deep breathing, dyspnœa, and slight cough. On palpation tactile fremitus was found diminished on the right side and percussion elicited a dull note at the base of the chest on the same side; auscultation revealed deficient breath-sounds, diminished vocal resonance, and a slight friction sound. Her temperature was 101° F. and her pulse was 100. These signs were taken to mean pleurisy with effusion. A couple of days later the effusion became very marked, respiration being much more distressing. Towards the end of the first week of the illness the fluid occupied about two-thirds of the pleural cavity and the temperature took on a hectic character. There was much sweating and the face assumed a very sallow colour, all the symptoms now pointing to empyema. At this stage the patient complained of an unpleasant taste, especially after coughing. It was decided to aspirate the chest, but before this could be done there occurred a violent fit of coughing and she expectorated about three pints of purulent material of a greenish-yellow colour, this being freely mixed with blood towards the end of the attack of coughing. The next examination of the chest showed the presence of air and fluid. The expectoration continued of the same character but gradually diminished in quantity till at the end of seven weeks from the commencement of the illness it had completely stopped, together with the cough. Pain was only felt on deep breathing. In less than three months from the date of her first symptom the patient was able to resume and carry on her duties satisfactorily. Two and a half years after this illness I took an opportunity of making a physical examination. There was no deformity resulting from her illness to be seen; the right shoulder drooped slightly, but not more than is usually met with in the majority of individuals. The breath-sounds were strong and movement on the right side of the chest was as good as on the opposite side. The only remaining trace of this illness was a slight friction sound on very deep inspiration. The woman expressed herself as feeling in excellent health and looked it.

Two points in connexion with this case seemed especially interesting—viz., the short time in which the effusion became purulent, there having been no antecedent illness, and also the quick recovery from the immediate as well as from the remote effects of a pyo-pneumothorax. With regard to treatment the measures employed were nothing out of the common. While expectoration lasted the patient frequently inhaled the vapour from a mixture of eucalyptus and thymol, the rest of the treatment consisting of a liberal diet with tonics.

Walthamstow.

NOTE ON A CASE OF COCCYGODYNIA; REMOVAL OF THE COCCYX; RECOVERY.

BY MONTAGUE D. MAKUNA, M.R.C.S. ENG., L.R.C.P. LOND.

AS cases of coccygodynia are infrequent and the pathology and treatment of that disease are still *sub judice*, I might be permitted to record a case of complete recovery by the removal of the coccyx.

A lad, aged eight years, came under observation during the first week in March, 1900, suffering from severe pain over the sacral region which deprived him of sleep and from inability to assume a sitting posture. This was associated with loss of body-weight and anorexia. On examination it was found that the coccyx was pointing backwards and downwards, its end touching a seat, so as to render a sitting position painful by the pressure of the soft parts and the skin between its point and the seat. On rectal examination it was discovered that the two lower segments of the sacrum were tilted inwards and that the continuity of the sacral curve was lost. This projection on the anterior surface of the sacrum could not be reduced under pressure, as what might be called the fractured surfaces were firmly but irregularly united. There was no clear history of injury and it is questionable whether this deformity in the sacrum was due to malformation or malnutrition. No operative procedure could be undertaken to reduce the deformity without doing considerable injury to the sacral nerves. While it was necessary that the coccyx should be removed to allow the lad to sit comfortably, I was in considerable doubt whether it would relieve him of his sufferings. He was kept in a recumbent

position and lactophosphates and anodynes were administered for nine weeks without any improvement. Under the circumstances I determined to remove the coccyx and, should this fail to relieve acute pain, to follow up the operation with treatment by osmic acid. On May 10th he was put under chloroform, the coccyx was pushed out through a straight incision in the median line, severed from the sacrum with a bone forceps, and, in order to prevent any damage being done to the diaphragm of the pelvis, dissected out from above downwards. There was no bleeding and the wound healed up rapidly under dry dressings. The patient is now able to sit comfortably, is free from pain, and is gaining flesh and vivacity.

Treherbert.

HYPERPYREXIA IN ACUTE RHEUMATISM.

BY HERBERT R. C. NEWMAN, M.B. DURH., M.R.C.S. ENG., M.R.C.P. LOND.

THE following case may be of interest as showing the efficacy of the early application of cold water to the body in the above condition. On April 30th I was called to a patient, a woman, aged 30 years, and found her suffering from acute rheumatism; she had pains in the limbs with profuse sweating and a temperature of 104° F.; a mixture of 20 grains of salicylate of sodium and 10 grains of bicarbonate of potassium was prescribed and taken every three hours. On May 1st her temperature was 102° and there was synovitis in the left knee- and ankle-joints. The salicylate was reduced to 15 grains every three hours. The case followed the usual course, both knees, the left elbow, the shoulder and finger joints being successively implicated until May 13th when the patient was free from pain and her temperature was normal. On May 16th the joint pains returned and the temperature rose to 101°. On May 20th the temperature was not elevated and there was no pain or sweating. On May 21st at 6 A.M. an attack of epistaxis occurred, at 7.30 A.M. there was a severe rigor, and the temperature at 11 A.M. was 107·8°. By this time the patient was drowsy and semi-comatose, with flushed face and dry skin; the pulse was 174, very weak and irregular. She was immediately wrapped in a sheet which had been placed in water at about 90° and suspended over a tub, being rapidly sponged with water which was cooled down gradually to 48°; this sponging was continued for five minutes at the latter temperature. The thermometer in the rectum then registering 102° she was dried and placed in bed again, being now quite conscious with the pulse 140 and fuller. At 3.30 P.M. the temperature was 104° and the pulse was 160; a 30-grain powder of salicylate was taken. At 10 P.M. her temperature was 106·5° and her pulse was 170; she was very restless and was again sponged until the rectal temperature was 101°. During the night she continued very restless and another 30-grain powder of salicylate was administered. On May 22nd when seen at 10 A.M. she was much better; her temperature was 102° and her pulse was 140 and full. At 8 P.M. her temperature was normal and her pulse was 124. From May 22nd to the 27th the temperature varied from normal to 102°, there was no return of articular pains, and she has made an uninterrupted recovery. A soft mitral systolic bruit was first heard on May 28th.

Chalford, Gloucestershire.

ST. GEORGE'S HOSPITAL HUNTERIAN SOCIETY.—The annual dinner of the St. George's Hospital Hunterian Society was held on June 8th at the Trocadéro Restaurant, Dr. H. D. Rolleston, the President of the society, being in the chair. In proposing the toast of "The Queen" Dr. Rolleston alluded to the comparatively large number of St. George's men now at the front in South Africa, not only as army and civil surgeons, but in the ranks of the Yeomanry and Volunteers. The health of the "Hunterian Society" was proposed by Mr. E. B. Turner, F.R.C.S. Eng., one of its oldest members, and that of the "Officers of the Society," proposed by Dr. J. Blumfeld, was responded to by Dr. A. C. Latham and Mr. Percival. Dr. G. A. Buckmaster (next year's president), Mr. George R. Turner, Mr. Herbert Allingham, and Mr. F. Jaffrey were representatives of the staff of St. George's Hospital who with a fair gathering of members of the Hunterian Society were present at the dinner.

WESTMINSTER HOSPITAL.

A CASE OF LYMPHATIC LEUKÆMIA OR LYMPHOCYTHÆMA TREATED SURGICALLY BY THE ESTABLISHMENT OF A COLLATERAL CIRCULATION.

(Under the care of Dr. W. MURRELL and Mr. WALTER SPENCER.)

THE establishment of a collateral circulation for the treatment of cases of ascites was first proposed by Drummond and Rutherford Morison in 1896,[1] and Morison has operated in three cases, the first of these operations being performed in 1894.[2] It has also been suggested by Talma,[3] who apparently did not know of the previous employment of this method.

A girl, aged 19 years, was admitted to Westminster Hospital on Nov. 7th, 1899, suffering from anæmia and amenorrhœa. She stated that she had been very anæmic for two years and for the last 18 months had been at home doing nothing. She had never been quite regular and for seven months the catamenia had been absent. There was considerable œdema of the lower extremities, but there was no ascites, she was not pregnant, there was no albumin in the urine, and there was no leucorrhœa. She was suffering from oligocythæmia with considerable oligochromæmia. The blood was of fair colour but appeared to be thinner than normal. The red blood corpuscles numbered 3,830,000 per cubic millimetre. The colourless blood corpuscles were 3000 per cubic millimetre, chiefly lymphocytes and finely granular oxyphile polynuclear leucocytes. She was ordered five grains of dried sulphate of iron in pill three times a day with a drachm of sulphate of sodium in hot water every morning. This was continued for a fortnight, but although she improved in strength and colour the menstrual function was not restored. On Nov. 28th she was ordered five grains of citrate of manganese three times a day, the dose being gradually increased until Dec. 8th, when she was given 15 grains four times a day. On Dec. 13th she menstruated, the period lasting two days. Four days later she left the hospital at her own request.

A few days after leaving the hospital the patient had a bad sore-throat and a cough unaccompanied by expectoration which kept her in bed for a fortnight. During this time her legs were swollen and her abdomen was greatly distended. She was re-admitted on Jan. 9th, 1900, when her temperature was 104° F. and the urine contained much blood and albumin. She had a soft apical systolic murmur conducted outwards to the axilla and round to the angle of the scapula. Her abdomen at the level of the umbilicus measured 34½ inches. It was resonant in front and on the right side, but on the left there was dulness extending from the groin to the lower margin of the ribs, and laterally from the flanks to within two inches of the umbilicus. Nothing was discovered on rectal examination and there was no indication of an ovarian cyst. There was a large quantity of fluid in the abdomen, probably confined by adhesions. The temperature during the first week always reached 101° in the evening, but there was no indication of tuberculous disease either in the lungs or in the larynx. The following report on the condition of the blood was received from the Westminster Hospital Clinical Laboratory under the direction of Dr. Lazarus-Barlow: "Blood taken from finger, 2 P.M. Drop pale and watery in appearance. Hæmoglobin, 65 per cent. Erythrocytes, 3,450,000 per cubic millimetre, of good size and shape. Leucocytes, 7000 per cubic millimetre, of which 54 per cent. are finely granular oxyphile cells and 3 per cent. are coarsely granular oxyphile cells. The remaining

[2] THE LANCET, May 27th, 1899, p. 1426.
[3] Berliner Klinische Wochenschrift, Sept. 19th, 1898, p. 833.

43 per cent. is made up of small cells having a single pale nucleus, which in most cases nearly fills the cell and is surrounded by a narrow zone of fine granules staining very deeply with methylene blue and when stained of a deep blue colour without purple tinge. For the most part, the cells are of about the size of lymphocytes, although they are totally different in other respects. A few cells have a larger amount of protoplasm, and these might as far as appearances go be hyaline leucocytes; against this is the presence in them of fine granules staining with a basic dye such as methylene blue. Upon the whole it is probable that these appearances are not artefacts and that the cells are basophile cells with fine granules." The patient passed daily about 30 ounces of urine, of specific gravity 1028, containing nearly one-half albumin and much blood. Urea, 2·5 per cent. No casts were found. The abdomen increased in size and at last became so distended as to cause the patient considerable discomfort. She was very feeble and her general condition was unsatisfactory.

On Jan. 27th Mr. Walter Spencer made an incision one and a half inches in length midway between the umbilicus and the pubes, from which about eight pints of slightly blood-stained fluid were drawn off. On exploration with the hand no disease of the abdominal viscera could be detected. A large glass drainage-tube was left in the abdomen and from this there exuded on the 28th, 34 ounces; on the 29th, 25 ounces; on the 30th, 45 ounces; and on the 31st, 30 ounces of blood-stained serous fluid. The tube was withdrawn on Feb. 5th and the wound was allowed to heal. On Feb. 12th the spleen was found to be enlarged, its lower edge being felt two inches below the ribs. The fluid in the abdomen gradually re-accumulated; the urine still contained large quantities of albumin, and the patient's general condition once more assumed a very unsatisfactory aspect. It was now determined to endeavour to establish a collateral circulation, and on Feb. 20th Mr. Spencer attached a piece of the omentum about two inches square to the anterior abdominal wall by kangaroo stitches. The vessels within the abdomen were congested and the veins were widely distended. On March 14th the superficial abdominal veins were noted to be larger. The wound was practically healed and there was no return of the distension of the abdomen. The mitral regurgitant murmur was more marked and in addition there was a loud systolic murmur heard most distinctly over the left second intercostal space and adjacent portion of the sternum. The albumin had disappeared from the urine. On April 19th the following report of the patient's blood condition was received: "Blood taken from finger 3.30 P.M. Hæmoglobin, 65 per cent.; erythrocytes, 3,000,000 per cubic millimetre; leucocytes, 4640 per cubic millimetre; finely granular oxyphile cells, 56 per cent.; coarsely granular oxyphile cells, 6 per cent.; hyaline cells, 20 per cent.; and lymphocytes, 18 per cent. The hæmoglobin value of each corpuscle is about 100 per cent. The erythrocytes are irregular in size and shape. Many of the hyaline cells and lymphocytes possess a granular cytoplasm, the granules staining with methylene blue. It is doubtful whether these are basophile cells or whether the appearance is artificial." The patient gradually improved in health and strength and was discharged on April 19th. The aortic murmur had disappeared and the mitral murmur was soft and very faint. On June 1st she was reported to be in good health.

Remarks by Dr. MURRELL.—There may be some difference of opinion respecting the nature of this case, but the diagnosis presents no difficulty. The patient when originally admitted was suffering from oligocythæmia and oligochromæmia, but the condition became one of lymphatic leukæmia or lymphocythæmia. It will be noted that when first admitted her leucocytes numbered only 3000 per cubic millimetre, but on the second examination they had risen to 7000 per cubic millimetre. The normal ratio of white to red corpuscles is 1 in 700, but in this case it is 1 in 493. The presence of finely granular basophile cells with the absence of non-granular cells is indicative of some pathological condition of the hæmatopoietic tissues. We find a diminution in the number of the red blood corpuscles and in some cases of leukæmia the condition is carried to an extreme degree so that they fall to 1,000,000 per cubic millimetre. The number of leucocytes varies in different cases, but the abnormal elements always persist. The essential change is the presence throughout the body of large numbers of small non-nucleated cells due to excessive proliferation. The infiltration of the hæmatopoietic tissue of the bone-marrow, with a gradual diminution of the blood-forming area, has resulted in anæmia. The muscular substance of the heart had probably undergone a form of degeneration from the deposition of fine granules within the fibres. The alteration in the composition of the blood played an important part in the production of the œdema by increasing the permeability of the vessel walls. The ascites was also due to the condition of the hæmatopoietic system, for as a result of venous stasis transudation from the peritoneum was taking place. The albumin in the urine may have been due to renal cirrhosis consequent on the long-continued interference with nutrition processes. The attempt in this disease to establish a collateral circulation is a new departure in surgery. The immediate result has been extremely satisfactory, but how far it will prove permanent remains to be seen. It must be remembered that the prognosis in cases of leukæmia treated by ordinary methods is extremely unfavourable. The administration in the early part of the case of a new soluble salt of manganese resulting in the re-appearance of the catamenia is worth mentioning.

Remarks by Mr. WALTER SPENCER.—Some cases, after repeated tappings for ascites, have been known to recover, no further peritoneal exudation occurring. Such recoveries have been attributed to the vascular anastomosis set up by the formation of adhesions between the viscera and parietes. Indeed, one has heard of the tapping immediately preceding the recovery having been followed by some septic peritonitis, and the existence of such adhesions has been frequently noted post-mortem. The clinical signs of the establishment of a vascular anastomosis through adhesions is the appearance of dilated veins over the epigastrium and wall of the thorax in which the current of blood is upwards. In marked cases of dilatation of the veins a fanciful comparison has been made with the Gorgon's head and its crown of snakes, "caput Medusæ." Hence have arisen attempts by surgeons to establish artificially such a vascular anastomosis in order to prevent the recurrence of peritoneal exudations. For this purpose adjacent peritoneal surfaces over the liver have been scratched or the spleen or omentum has been fixed in the abdominal wound. There appears to be no special danger connected with such operations. The adhesions are well above the umbilicus, so that there is no probability of a coil of intestine becoming strangulated beneath the band; for the same reason the gap in the abdominal wall is not likely to lead to a ventral hernia. The operation is at present an empirical, in other words an experimental, one. The pathological explanation of the production of the peritoneal exudation and of its prevention by establishing a visceroparietal vascular anastomosis is not yet sufficiently clear.

LEEDS GENERAL INFIRMARY.

A CASE OF STRANGULATED FEMORAL HERNIA IN WHICH GANGRENE WAS PRECIPITATED BY AN INTRA-ABDOMINAL VOLVULUS.

(Under the care of Mr. R. LAWFORD KNAGGS.)

THE following case is an example of a condition to which until recently very little attention has been devoted. In all cases of volvulus some condition must be present which will fix the bowel in the abnormal position, otherwise the intestine will spontaneously untwist. In many cases of volvulus the weight of included fæcal matter is sufficient to effect the fixation; in the case recorded below the entrance of the loop of bowel into the hernial sac prevented the spontaneous reduction of the volvulus. An interesting case is related by Mr. R. W. Parker[1] in which a volvulus complicated a strangulated femoral hernia but in which there was apparently no causal connexion between the two conditions.

A woman, aged 61 years, who had worn a truss for a left femoral hernia for many years, was admitted into the Leeds General Infirmary on Jan. 6th, 1900. Six days previously the rupture had come down and could not be put back and severe pain and vomiting immediately followed. The bowels had not been opened since. Three days before admission she had been urged by a medical man to go into the infirmary to undergo an operation, but she had resolutely declined. When at last she consented the tumour was of the size of an orange, ill defined, and very tender, and the overlying tissues were red and œdematous. The pulse was 100 and the tongue was moist.

Without delay herniotomy was performed. The sac was found to be gangrenous and infiltrated with pus and adherent

[1] Transactions of the Clinical Society of London, vol. xxvii., p. 189.

to a knuckle of small intestine which was quite dead and did not bleed when incised. There was no fluid in the sac. On opening the bowel no escape of contents occurred, and on attempting to pass a director along the lumen of the gut it could not be introduced beyond the ring. All pus was now carefully wiped away and the parts about the sac were made as clean as possible, and the incision was extended upwards through Poupart's ligament so as to expose the bowel at the entrance to the ring. An interesting disposition of parts was at once revealed, fully accounting for the failure to pass the probe upwards and for the absence of relief. The loop contained in the hernial sac constituted the chief portion of a small volvulus, the neck of which lay just within the abdominal cavity close up against the femoral ring. The twist was one of 180 degrees from right to left and the distended bowel above the twist hung down into the pelvis, whilst the empty bowel coursed directly upwards upon the psoas and iliacus muscles. At the neck of the volvulus the upper end of the loop lay superficial to the lower end. The twist, which constituted a very effective obstruction, was undone and the gangrenous loop was removed, the two extremities being united over a Robson's bobbin. The gangrenous sac was also removed and the wound was closed except for a gauze drain which was inserted down to the seat of union. The patient was completely relieved of vomiting and pain and was able to pass flatus, but death took place 26 hours after the operation from gradual cardiac failure.

Necropsy.—At the post-mortem examination the united bowel was found to be in a satisfactory condition and no unhealthy peritonitis was present. The kidneys were granular and in an advanced stage of disease.

Remarks by Mr. LAWFORD KNAGGS.—Probably most surgeons who have had a considerable hospital experience can call to mind cases of gangrenous herniæ in which after the bowel has been laid open with intent to produce an artificial anus no relief has taken place. Such a case fell to my lot a year or more ago, and after 24 hours I had to open the abdomen above Poupart's ligament and make an opening in the distended coil above the hernia to obtain a relief which unfortunately came too late. At the time of the second operation the cause of the continuance of the obstruction was not made out, and no satisfactory explanation was forthcoming after the post-mortem examination, at which, unfortunately, I was unable to be present. The case recorded above, therefore, from this point of view alone is of considerable interest.

There can be little doubt that in this case the volvulus exerted a determining influence in the production of gangrene of the herniated intestine. For years probably bowel had entered the sac at intervals and had been replaced without harm. On this occasion a small loop chanced to enter in a reversed position and the traction exerted upon the intra-abdominal ends of the loop led to them becoming tightly crossed as in a figure 8 close up to the femoral ring. Immediately an obstruction was formed, not only to the passage of the intestinal contents but to some extent, no doubt, to the circulation. Rapid distension of the loop and engorgement of its coats ensued, and a further and more rigid interference with the circulation resulted as the femoral ring began to restrain the expanding and swelling gut. The onset of these changes must have been rapid, for one is justified in assuming that gangrene quickly supervened from the fact that fluid, with the exception of a slight smearing of pus, was entirely absent from the sac.

Elsewhere [2] I have attempted to study the subject of volvulus as it is met with in connexion with herniæ and I have been able to recognise four well-marked groups of cases. The present case, which was met with after my first paper had been accepted for publication, is an excellent example of the first group. That group includes those cases of volvulus in which the neck lies within the sac, or outside it but close to the ring. Now, though when dealing with the subject generally both these sets of cases were classed together for pathological reasons, yet it is clear that from the clinical standpoint the relation which the neck of the volvulus bears to the neck of the sac is a matter of no small importance. When the neck lies within the sac the exact nature of the condition is at once apparent when that is opened, and the twist can be undone and the bowel returned, if fit, as in the ordinary operation for strangulated hernia. But if the neck of the twist lies close to the ring within the abdomen, its existence may not even be suspected, and if the gut is gangrenous, as is most likely where the rupture is of the femoral variety, and the case is dealt with by the formation of an artificial anus, an abiding obstruction will be left and no relief will take place. Such a condition is, however, now less liable to be overlooked because resection of the gangrenous loop is becoming more and more the rule. But should it be decided for any reason to form an artificial anus, if no relief takes place when the bowel is opened and if the director cannot be readily introduced within the bowel well beyond the ring, then the incision should certainly be extended to investigate the condition of parts within the abdomen, and with the intention of removing the damaged gut.

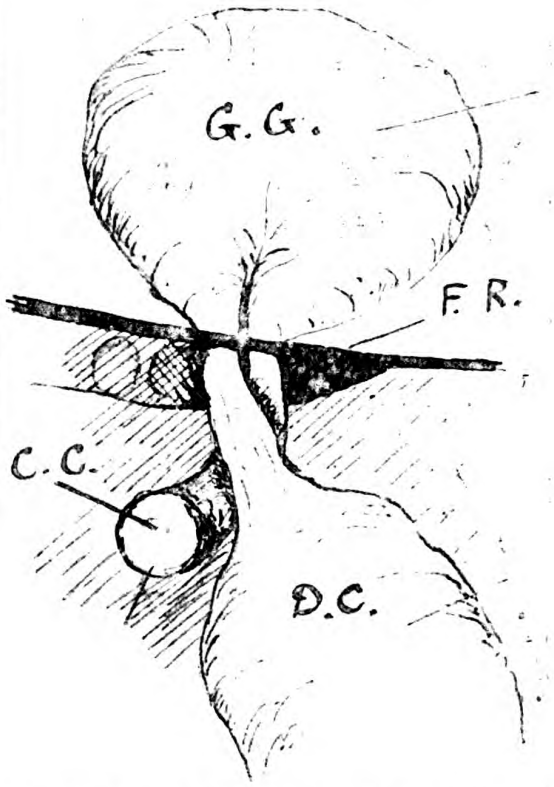

Diagram showing the position of the parts found at the operation. G.G., Gangrenous gut. F.R., Femoral ring. D.C., Distended coil of gut hanging into the pelvis. C.C., Contracted coil of gut directed upwards over the psoas muscle.

It is a simple thing for a loop of bowel to enter the hernial sac in the reversed state, but when once it is engaged the twist may easily become effective. In femoral herniæ under such circumstances the danger of gangrene is greatly increased. It is probable that such a disposition of parts as is shown in the diagram is not infrequent. Its importance is obvious, and it is certainly one that might easily be overlooked or disarranged in making a post-mortem examination.

The want of success in this instance was due entirely to the co-existence of advanced renal disease which would almost certainly have prevented recovery after any operation of importance, but which, even if detected in time, could not have been held to justify non-interference in strangulated hernia.

THE INFIRMARY AT BRECHIN.—The Chairman, at a meeting of the directors of this infirmary, held on June 4th, announced the receipt of a donation of £1000 from Mr. Duke, Bearchill, which is to be applied in helping to pay the cost of maintaining two beds in the name of Mr. Duke and his wife.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Alterations in the By-laws.—The Medical and Surgical Complications of Pyorrhœa Alveolaris.

A MEETING of this society was held on June 12th, Dr. F. W. PAVY, the President, being in the chair.

On the recommendation of the council several important alterations in the by-laws were put to the meeting and carried. The effect of these was threefold—viz.: (1) that the publication of the "Proceedings" would in future cease; (2) that the restrictions which had hitherto prevented Fellows from publishing communications made before the society in any other medical journal or periodical would be removed; and (3) arrangements would in future be made for the publication in the Transactions of the society of reports of the debates on papers read at the meetings.

Mr. RICKMAN J. GODLEE read a paper on some of the Medical and Surgical Complications of Pyorrhœa Alveolaris. He commenced by remarking that although the complaint was a very common one it did not apparently very often give rise to serious symptoms. Pyorrhœa alveolaris or Riggs's disease consisted of a spongy condition and recession of the gums, accompanied, and perhaps caused, by the deposit of tartar around the teeth. The inflammation extended to the peridental membrane or periosteum of the fang with the result that suppurating pockets were formed between the peridental membrane and the tooth. Some held that it depended upon the presence of some special micro-organisms; but the accuracy of this statement had not been established. The disease was one of adult life; it was often apparently hereditary, chronic, and very difficult of cure. Though not usually the source of serious trouble it might give rise to symptoms that simulated those of more grave disorders. Of these, three examples were given from Mr. Godlee's own experience and one from that of Dr. Sidney Martin. The first case was that of a woman, about 40 years of age, in whom a copious offensive red expectoration occurred. She had been the subject of pleurisy and some renal trouble. A few physical signs were present on the right side of the chest, giving rise to the suspicion of a basic cavity. The symptoms disappeared on the effectual treatment of the gums and the digestion and general health improved remarkably. The second case was that of a married woman, aged 25 years, which resembled the first case in many respects. Examination of the expectoration showed that it contained, like the first case, a large quantity of squamous epithelium and separated into two layers. After adequate treatment directed to the gums she lost all her troublesome symptoms. The third case was that of a man, aged 66 years, who presented the disease in a very advanced condition and was attacked by acute glossitis and stomatitis with diarrhœa and pyrexia. These were apparently caused by the state of the gums, for they disappeared when the condition of pyorrhœa alveolaris was remedied. In the fourth case, that of a woman, aged 43 years, the symptoms of cancer of the stomach were apparently caused by pyorrhœa alveolaris; but all the symptoms disappeared when the gums had been effectually treated. In the course of the paper the question of treatment was briefly discussed.

Dr. JAMES DONELAN remarked that the subject was one of considerable interest. Referring to the supposed presence of uric acid in the gums he believed the condition of pyorrhœa alveolaris often had a constitutional origin. He mentioned the case of a man, aged 64 years, a great sufferer from gout, who for some years presented a marked condition of pyorrhœa alveolaris. Whenever this was neglected the symptoms recurred again, but when this was attended to he remained well. In another case, that of a man between 26 and 30 years old, pyorrhœa alveolaris was attended by enlargement of the cervical glands; when the gums were neglected the glands enlarged, but they subsided when these were treated. He believed that sufficient attention was not paid to the teeth in these cases of glandular enlargement.

Dr. GEORGE E. HERMAN referred to the case of a woman from whom he had removed a pyosalpinx in April. During the following week the temperature was raised every day to between 100° and 101·8° F. This could not be attributed to the operation in any way. The patient was found to be suffering from pyorrhœa, and nine days after the operation a dentist was called in who prescribed an antiseptic mouth-wash when the temperature (of which a chart was shown) immediately subsided to normal.

Mr. W. G. SPENCER asked for a more precise definition of the disease and what degree of pyorrhœa was necessary to produce these symptoms. Patients had sometimes come to him for throat affections in which the teeth might have been the source. He had seen cases of muco-purulent pharyngitis set up by a bad state of the teeth and gums. He desired to emphasise the necessity of constant treatment. A persistent dressing of the teeth by the patient should be insisted on. He had recently had a case of pyosalpinx under his care with pyorrhœa alveolaris which had produced anæmia, and he had seen septic conditions set up entirely by bad teeth.

Dr. T. D. SAVILL remarked that he could not agree with Mr. Godlee in thinking that pyorrhœa alveolaris did not give rise to serious symptoms. Very serious nerve symptoms of the class called functional might be produced by the condition. A woman, aged 32 years, consulted him recently with all the symptoms of aggravated hysteria on which the usual remedies had no effect until some stumps concealed beneath her artificial plate had been removed, when she made a rapid recovery. Another case was that of a professional man who gradually drifted into melancholy and committed suicide. A third case was that of a woman suffering from trifacial neuralgia of four years' duration which remained wholly unrelieved until the suppurating sockets of her teeth were properly attended to. In quite a large proportion among his out-patients at the West-end Hospital for Diseases of the Nervous System the cause could be traced to pyorrhœa alveolaris, and among the symptoms they presented were listlessness, restlessness, a sense of fatigue, tingling of the extremities and actual œdema which differed from ordinary anasarca in requiring more prolonged pressure to produce the pitting, headache, shivering attacks, nervousness, irritability, depression, dyspepsia, and a number of others.

Mr. C. S. TOMES remarked that the prominent place assigned to the expectoration as a symptom by Mr. Godlee was not in accordance with his experience. The expectoration and discharge from the gums were usually swallowed and were therefore not prominent features in an average case. It was only at night that any bloody fluid ran out and stained the pillow. In answer to the questions, What degree of pyorrhœa was necessary to produce symptoms? and how did the condition differ from senile conditions of the gums? if without obvious cause pressure along the margin of the gums caused purulent fluid to come out of the sockets of the teeth pyorrhœa alveolaris was present; and this was sufficient to produce symptoms. Referring to the question of treatment, antiseptics applied between the tooth and the gum greatly improved matters at once, but this did not always last. Another form of treatment was that originally practised by Riggs which consisted of scraping away the margin of the alveolus. It was a very tedious and painful operation. This for a time also relieved, but here also relapses occurred. The disease occurred in animals as well as in mankind. Persons suffering from the disease presented a very characteristic sallowness. If a tooth were extracted from an affected socket it was extremely rare for the wound to go wrong, strange as this might seem. As to the presence of urates in the tartar there was no reliable evidence in this matter and fallacies were numerous, especially in the murexide test, which was the one that had been employed.

Dr. W. EWART remarked that this debate demonstrated the value of having a jointly medical and surgical discussion. Many men were very familar with the far-reaching effects of this disease, though the symptoms were not described in books. Some of the symptoms belonged to the so-called functional neuroses and the effects so produced might be sufficient to ruin the life of the individual as a wage-earner or useful member of society. The symptoms, however, were eminently curable. He wished particularly to take exception to the statement that the disease did not lead to serious consequences. He wished to refer to one or two in particular. The fœtor of bronchiectasis was largely dependent, he believed, in some cases at any rate, on infection from the mouth. He believed that pyorrhœa alveolaris was also capable of generating malignant endocarditis. He considered that many cases of so-called primary malignant

endocarditis might be explained in this way—viz., the source of infection being in the mouth. He thought that three cases he had recently seen were probably instances of this mode of causation.

Mr. WILLIAM HERN discussed the question whether the pyorrhœa was of constitutional or local origin. Patients were often suffering from gout or rheumatism or some other constitutional condition, but in his belief it more often had a local origin. The malady frequently started from one or two teeth. It rapidly improved under local treatment, especially antiseptic measures, and if the affected tooth were extracted the disease came at once to an end. He had seen cases of acne rosacea improve after effectual treatment of the concurrent pyorrhœa.

Mr. W. B. PATERSON referred to the case of a married woman, aged 35 years, who for two years had been under medical treatment for a purulent discharge which she said she coughed up. She was treated by many different specialists for disease of the nose, the pharynx, the ear, and finally the mastoid cells were trephined; but at the end of two years, after spending a fortune in medical advice, the pyorrhœa was treated daily for a week and she improved at once.

Mr. GODLEE, in reply, said the discussion had brought out a large number of interesting facts. A desideratum was, however, still wanting in a satisfactory method of treatment which the patient could employ himself. He had seen tuberculous glands in the neck develop as a result of pyorrhœa. As to the presence of squamous epithelium in the sputum this could always be obtained in large quantity from the saliva, especially when the patient sucked his gums.

OBSTETRICAL SOCIETY OF LONDON.

Extra-Uterine Gestation.—Exhibition of Specimens.

A MEETING of this society was held on June 6th, Mr. ALBAN DORAN, the President, being in the chair.

The PRESIDENT read a paper on a case of Extra-Uterine Gestation in which Fœtal Death occurred at the eighth month after Spurious Labour; Abdominal Section two months Later. The patient, aged 34 years, became pregnant for the fifth time, after an interval of four years, in February, 1899. Abdominal pains occurred early; diarrhœa caused trouble from July to the end of October, when labour pains and hæmorrhage set in, followed by septic symptoms. The outline of a fœtus could plainly be felt through the parietes. On Dec. 12th it was removed by abdominal section. It was very fœtid and had developed in the posterior layer of the right broad ligament. The sac was packed with gauze for a few days and then drained; the placenta came away in fragments. A fæcal fistula developed and discharged for a few weeks. For six weeks the patient did very well, then symptoms of chronic obstruction with great emaciation set in, and she died in the ninth week after operation, flatus passing to the last. Several coils of small intestine had been dragged upon by the contraction of the sac; the adhesions involved several surfaces of mesentery, which seemed to account for the emaciation, strongly marked in this case, where there was but little vomiting or distension. The President dwelt on the infection of the sac, especially common in posterior tubo-ligamentary pregnancy (Taylor), on the diarrhœa observed when placenta was attached to intestine (Freund), and on the inanition caused by the changes noted in this case. As there was no true sac-wall inferiorly in this form of ectopic gestation complete extirpation of the sac seemed hardly possible. He dwelt on Dunning's case and on those collected by Jayle and Delherm, and expressed doubts as to the precise anatomical character of the sac in some of these cases. Finally, the President agreed with Taylor in preferring to pack and drain the sac, but did not know of any method of dressing which could obviate the dangers which followed the contraction of the sac-wall.

Mr. BUTLER-SMYTHE said that in this particular case the fœtid contents of the sac would alone have prevented any attempt at enucleation. He considered that the patient's life had been prolonged owing to the treatment adopted by the President, who repeatedly washed out the sac with a strong solution of iodine before closing the wound. He (Mr. Butler-Smythe) advocated this method in all similar cases.

Dr. C. J. CULLINGWORTH congratulated the President on his paper and wished to endorse his opinion of the great value of Mr. J. W. Taylor's recent work on extra-uterine gestation. He agreed with him that although the ideal method of dealing with the sac was to remove it there were cases, such as the one under discussion, where such a procedure was impracticable. If the sac were left free drainage was important, but he disapproved of packing the cavity with gauze, especially in the case of a necrotic gestation sac. Gauze-packing was, however, useful for checking hæmorrhage or for the prevention of secondary hæmorrhage. He considered that antiseptic irrigation of a necrotic gestation sac might temporarily deodorise, but could not disinfect, its walls. Moreover, irrigation had its dangers and putrid matter might be carried through lesions in the continuity of the sac-wall to adjacent structures. Irrigation as a routine practice in gynæcological surgery should be less generally adopted. He considered that Freund's view which the President had adopted, that the diarrhœa in these cases was an indication that the placenta was attached to intestine, was not always correct, and that the diarrhœa was partly the result of irritation from pressure and was partly one of the symptoms of septic infection. This case bore out his opinion that spontaneous closure of fæcal fistulæ might always be reasonably hoped for when they were not too low down in the rectum and when the subjects were free from tubercle or malignant disease. He did not believe that this patient's life could have been saved by any treatment.

Mr. J. D. MALCOLM had seen the patient before and during the operation and thought that the President had, if anything, understated her extreme emaciation and debility. The development of fæcal fistulæ within a few days of the operation proved that it would have been impossible to remove the sac. He agreed with Dr. Cullingworth that washing out the abdomen was done too frequently, but in this case with a putrid cavity and much sloughing placental tissue on its walls it was most necessary. As regards the mode of death, judging by the alternate distension and flattening of the abdomen, he thought there must have been an escape of gas from the upper bowel as long as the patient lived. Thus the symptoms were not those of obstruction of the bowels, although an obstruction, with a fistula, actually existed, and death was due to exhaustion and malnutrition.

Dr. ROBERT BOXALL had twice seen a fæcal fistula heal in the same patient when in a serious condition of ill health from a suppurating dermoid tumour. It was an important fact that such fistulæ would sometimes heal even when the patient was seriously ill. He suggested that a rubber bag (like a child's balloon) might with advantage be substituted for gauze packing. By attaching a tube and funnel and filling with solution pressure could be regulated to a nicety. It could be emptied by syphoning out the fluid and easily refilled, thus avoiding the disadvantages of repacking.

The PRESIDENT noted that Tait's "abdominal pregnancy" was a tertiary change, as Taylor had ably demonstrated; a tubal sac burst in the first place between the layers of the broad ligament and afterwards this secondary intra-ligamentary pregnancy burst into the peritoneal cavity. Taylor distinguished a more frequent secondary form of abdominal pregnancy. The President's own case was one of the typical "posterior tubo-ligamentary" varieties of Taylor. He was relieved to find that the society supported him in his opinion that no attempt should have been made to remove the sac. In that case the diarrhœa prevailed before the death of the fœtus, and the placenta was, in fact, attached to the rectum. These facts supported Freund's theory. Pure tincture of iodide, as Mr. Butler-Smythe had observed, was an excellent application for an irremoveable fœtid cyst-wall. He was compelled to wash out the sac freely on account of the fragments of placenta and fæcal matter which it contained. Antiseptic lotions stimulated the exposed tissues and caused granulations to develop, yet ulceration or sloughing might occur in very sickly cases, as Dr. Cullingworth, who objected to lotions, had implied. He had removed the packing within a few days. Dr. Boxall's suggestion that the sac might be prevented from too rapid contraction by means of an inflatable thin rubber bag seemed worth a trial. The fistula was low down in the rectum. In conclusion, the President feared that the operator must still depend more than he cared for on luck, as no certain method for preventing the dangers due to contraction of an irremoveable sac of this kind was at the operator's disposal.

The following specimens were shown:—

Dr. W. S. A. GRIFFITH: (1) Squamous-celled Epithelioma

of the Cervix Uteri in a Very Early Stage; and (2) Squamous-celled Epithelioma Invading Surrounding Tissues like a Columnar-celled Variety.

Dr. H. RUSSELL ANDREWS: Sarcoma of the Uterus.

Dr. HUBERT ROBERTS: (1) Large Cystic Fibro-myoma Adenoma of the Cervix Uteri; and (2) Microscopical Sections Illustrating Various Forms of Uterine Adenoma.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Tubal Pregnancy.—Pan-Hysterectomy.—Delivery of the Placenta.

A MEETING of this section was held on May 25th, Dr. A. V. MACAN, the President, being in the chair.

Dr. ALFRED SMITH showed a specimen of Ruptured Tubal Pregnancy, consisting of the distended tube showing rupture, the fœtus (three centimetres long), with umbilical cord and placenta. It was removed from a patient, aged 33 years, who had given birth to a full-term child six months previously. Menstruation returned one month after confinement and continued regularly up to the time of rupture; no period had been missed. The patient was brought to Dublin from Kilkenny. Convalescence was normal.

Dr. F. W. KIDD read notes of a successful case of Pan-hysterectomy performed on the Pregnant Uterus at Full Term. The patient was a primipara of over 40 years of age. The presenting part could hardly be reached owing to the whole of the true pelvis being blocked with myomatous growths and no definite diagnosis of the presentation could be arrived at. An abdominal incision was made extending from two inches above the pubes to two inches above the umbilicus. The broad ligaments were first ligatured and then cut, then the round ligaments, and then the peritoneum on the outer surface of the uterus was divided transversely and stripped down, taking the bladder with it; the uterine vessels were tied, and when the peritoneum had been stripped down posteriorly the vagina was cut across as close to the presenting head and arm as possible. The vagina was inverted and sutured, turning in the mucous membrane, the broad ligaments were brought together, and in the middle line the peritoneum attached to the anterior surface of the bladder was sutured to the peritoneum on the posterior wall of the vagina, completely covering over the stump of the vagina and leaving the pelvis quite clean and dry; the ligatures on the uterine vessels had been drawn down before the peritoneum was stitched over them. The patient made a good recovery. The specimen, which was exhibited, contained the child in the uterus, only the head and one shoulder having escaped from it. The method of preserving the specimen was as follows:—Fluid No. 1: formalin, 10 parts; acetate of potash, 15 parts; chloride of potash, 0·5 part; water, 100 parts. The specimen was placed in this for 48 hours, changing at the end of 24 hours. Fluid No. 2: methylated spirit, 80 parts; water, 10 parts. The specimen was placed in this for 48 hours, changing at the end of 24 hours. Fluid No. 3: pure methylated spirit. The specimen was placed in this for 48 hours. Fluid No. 4: glycerine, 20 parts; acetate of potash, 10 parts; water, 100 parts. The specimen was preserved permanently in this.

Dr. HENRY JELLETT read a paper entitled, "The Dublin Method of Effecting the Delivery of the Placenta." He commenced by remarking that in 1876 two well-known medical writers called attention to the fact that the method of effecting the delivery of the placenta by external manipulations, as opposed to its manual removal or to its delivery by traction upon the funis, had been first introduced in Dublin, and that it was identical with the method of obtaining the same object which had been introduced at a later date in Germany by Credé of Leipsic. In 1900, all German, and the great majority of British, works on midwifery term this method "Credé's method," while the few works which allude to the fact that the Dublin school of midwifery had some share in introducing this most important improvement in the management of the third stage consider that there is a difference between the Dublin method and Credé's method. He said that his paper was written to prove: (1) that the method of obtaining the delivery of the placenta by external manipulations as opposed to its manual removal or its delivery by traction on the funis was originated in Dublin; (2) that Credé's method was identical in principle with the Dublin method and that it rapidly came to assimilate itself to the Dublin method in its most important details; and (3) that consequently there is no difference between the Dublin method and Credé's method and that inasmuch as the method originated in Dublin many years before the time that Credé discovered it for himself its name is, and ought to be, "the Dublin Method." Dr. Jellett then described the gradual evolution of the Dublin method of effecting the delivery of the after-birth from the time of Fielding Ould up to the time of Sinclair and Johnston. He then described Credé's method in Credé's words as taught by him in 1853, and said that in 1860 Credé brought his method prominently before the German medical world at a meeting of the Association of Physicians and Naturalists held in Königsberg. In Dublin the method had been practised clinically at the Dublin Lying-in Hospital from time immemorial.—Dr. W. J. SMYLY said that they should be thankful to Dr. Jellett for the proofs which he had brought forward. Nevertheless, he thought that there was a distinction between Credé's method and the Dublin method. The fault of Credé's method was that it was too active and if they expelled the placenta too soon they might leave portions behind leading to post-partum hæmorrhage and sub-involution. Another point likely to be lost to the Dublin school was the method of preserving the perineum, generally known as von Ritgen's method, which undoubtedly originated in Dublin.—The PRESIDENT said that the question was whether the Dublin method was the same as Credé's. As far as he could see the Dublin method differed in that in it the hand was applied to the abdomen and pressure begun as soon as the child's head was born, the pressure being used to express the shoulders and then continued to expel the placenta. He wished to emphasise the fact that the Dublin method began before the third stage of labour—namely, the moment the child's head was born. He was convinced that in the great majority of cases the third stage of labour should be left alone as well as the second stage.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on May 15th, Mr. W. H. Horrocks, jun., being in the chair.—Dr. C. C. Baxter-Tyrie read notes on a case of Thoracic Aneurysm. The patient was a man, aged 51 years, whose illness commenced about two years previously. While engaged in valuing some stock on a farm he jumped about eight feet down into a field and "felt something give way" in the lower sternal region and at once became faint. He was taken home and an hour afterwards he expectorated about a teacupful of pure blood. Physical examination revealed no abnormal signs except rhonchi at the bases of the lungs. There was no return of the bleeding and after a few months the man apparently recovered, although from time to time there was an irritating cough and some oppression at the chest. Five months before he died œdema of the lower extremities was noticed; there was much wasting and the patient complained of a constant irritating cough and of dyspeptic symptoms. There was pain in the epigastrium which passed through to the back and at times extended round the body, following the course of the eighth and ninth dorsal nerves. There was accentuation of the second sound of the heart, otherwise the physical examination of the heart area showed nothing abnormal. There was no alteration in the radial pulses, no pupil change, no dysphagia, and no alteration in the mobility of the trachea. A constant irritating cough was present but there was no peculiarity in its intonation. There was occasional paroxysmal dyspnœa with inspiratory stridor. From time to time small quantities of blood came up into the mouth without effort. The patient died suddenly while in bed from profuse hæmorrhage. There was no necropsy.—Dr. J. Kerr, Dr. H. J. Campbell, and Dr. H. C. Major discussed the case and Dr. Baxter-Tyrie replied.—Dr. R. H. Crowley read a paper on Uræmia. It was concluded that all cases of uræmia were due to the retention of some toxic substance or substances in the blood which should have been excreted by the kidneys. The poison might not be always the same, nor was its non-excretion necessarily due to renal inadequacy alone. In regard to treatment it was urged that preventive treatment was of the first importance in all cases in which it was likely or possible that uræmia might occur. Attention to the free action of the bowels and of the skin together with

regulation of the diet were most important from the point of view of prevention. During a mild uræmic attack where there was much vomiting the use of an enema of magnesium sulphate was advocated as being of great value. In using the hot vapour bath the danger was mentioned of prolonging it in cases where sweating was not soon induced. To promote sweating the careful use of pilocarpine in doses of one-tenth of a grain was advocated, the patient being first put into a hot pack and a copious draught of hot tea having been administered. In some cases of convulsions, in eclampsia, and where there was a high-tension pulse the withdrawal of 20 ounces of blood was often followed by very marked relief. Lavage of the stomach was alluded to as a means of treatment which was neglected somewhat in England, and which was likely to give beneficial results. The injection of saline fluid, either directly into a vein or preferably into the loose subcutaneous tissues, was favourably spoken of.—Mr. W. H. Horrocks, jun., read a paper on the Medical History of Gibbon the Historian.—Specimens were shown by Dr. S. Lodge, jun., and Dr. R. H. Crowley.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on May 18th at the Medical School, Leopold-street, Sheffield, the President, Dr. J. B. Hellier, being in the chair.—Dr. H. Briggs (Liverpool) showed numerous specimens and water-colour drawings illustrating the various types of villous endometritis, and of benign and malignant adenoma of the uterus. He alluded more particularly to the difficulty of deciding upon the microscopic evidence between inflammatory conditions of the endometrium and malignant adenomatous disease of the uterine glands and quoted several illustrative cases.—Remarks were made by Dr. A. Donald (Manchester) and Dr. Martin.—Dr. Donald showed a Uterus with Multiple Fibroids and containing a fœtus of four and a half months' development. The tumours were situated in the pelvis, below the fœtal sac, and would have obstructed labour. The whole mass was successfully removed by abdominal hysterectomy. —The President showed a Large Dermoid Cyst with a twisted pedicle successfully removed by abdominal section.—Dr. A. W. W. Lea (Manchester) read a paper entitled the Influence of Gonorrhœa on the Puerperium, with Notes of 50 Cases. The diagnosis of gonorrhœa at the time of labour was based upon the occurrence of ophthalmia neonatorum in the infant within three days of delivery, combined with the previous clinical history of the case. The puerperium was normal in 60 per cent. of the cases, as judged by the absence of pyrexia. In four of these, however, at the fourteenth day there was some evidence of pelvic inflammation. In two cases there was perimetritis with swelling in the region of the appendages, and in two cases parametritic exudation was present. In 40 per cent. of the cases the puerperium was abnormal, characterised by pyrexia, often severe, together with symptoms of local infection of the genital tract. The rise of temperature usually commenced on the third or fourth day after delivery and was usually associated with purulent discharge from the uterine cavity. In many of the cases the infection remained limited to the uterus, but in five instances (10 per cent. of the total number) acute pelvic peritonitis ensued with a severe illness lasting some weeks. Details were also given of three cases in which a previously existing gonorrhœal infection of the appendages became virulent during or immediately after labour, each case terminating fatally. From a study of these cases and a review of the literature of the subject the following conclusions were drawn:—1. The presence of a purulent vaginal discharge during labour which was capable of causing ophthalmia neonatorum rendered the patient liable to puerperal infection. 2. This infection was in many cases a mixed one, the gonococcus being associated with staphylococci and streptococci. The gonococcus itself was capable of causing severe infection and might be obtained in pure culture from the cavity of the uterus (Kronig Bumm). 3. Lacerations of the perineum, vagina, or cervix, forceps deliveries, and prolonged labour greatly increased the liability to infection. 4. The types of disease met with were—(1) purulent endometritis, (2) acute pelvic peritonitis with metritis, (3) acute parametritis, and (4) septicæmia (rare). 5. In some cases an old infection of the appendages might light up during labour or after delivery leading to acute peritonitis which might be fatal. 6. The prognosis as to life was usually good, though recovery was often imperfect. 7. The treatment by vaginal douches after labour was insufficient in many cases to prevent infection of the endometrium. 8. If infection of the uterus occurred uterine douches should be given daily, the patient maintained at absolute rest, and a careful watch kept for evidence of localised pelvic peritonitis. If douches failed to control the infection the uterus might be explored and curetted if there was evidence of retained products or hypertrophy of the decidua. Cases of localised pelvic peritonitis requiring operation should be treated by vaginal section.

Reviews and Notices of Books.

Heart Disease with Special Reference to Prognosis and Treatment. By Sir WILLIAM H. BROADBENT, Bart., M.D., F.R.S., F.R.C.P. Lond., &c., Physician Extraordinary to H.M. the Queen, Physician in Ordinary to H.R.H. the Prince of Wales, Consulting Physician to St. Mary's Hospital and the London Fever Hospital; and JOHN F. H. BROADBENT, M.A., M.D. Oxon., M.R.C.P. Lond., Medical Registrar to St. Mary's Hospital. Third edition. London: Baillière, Tindall, and Cox. 1900. Pp. 420. Illustrated. Price 12*s.* 6*d.*

ADVANTAGE has been taken of the call for a new edition of this work to bring it fully up to date, and with this view chapters on Acute Affections of the Heart, Endocarditis, Pericarditis and Myocarditis, and on Aneurysm of the Arch of the Aorta have been added. The authors do not profess to give a systematic and complete treatise on each subject or to enter into a discussion regarding the conflicting views which have been entertained on various points of pathology and etiology; their object has been rather to endeavour to place before the reader a clinical picture of each disease and to emphasise the points which are of chief importance in diagnosis and prognosis. Taken from this practical standpoint the work contains a vast amount of information which should prove most useful to the practitioner. Patients are naturally anxious to know what will probably be the result and length of the illness from which they are suffering, and particularly is this the case with any trouble affecting the heart. The sufferer cares but little whether a certain cardiac murmur which the physician hears is congenital or the result of infantile rheumatism, but he has the most supreme interest in trying to ascertain to what the cardiac condition is likely to lead. The chapters on Prognosis are about the best in the book. The style in which they are written is clear and precise and the practitioner having carefully studied them will feel in a position to fully explain to his patients the probable results of the affections of the heart with which they may be unfortunately affected.

The subjects of Hypertrophy and Dilatation of the Heart receive considerable notice and we would especially draw the attention of readers to the chapter which deals with these conditions. The most important indications as to the extent of a valvular lesion are to be gathered from its effects on the walls and cavities of the heart, resulting in hypertrophy of the former and dilatation of the latter. Sir William Broadbent's remarks are the result of careful study and large experience and they will consequently be read with a confidence inspired by their origin.

We are informed in the preface that the chapters on the Inflammatory Affections of the Heart are entirely the work of Dr. John Broadbent. These conditions have been more carefully studied during recent years and are therefore more fully understood than they were formerly, and the author has given a good summary of the advances which have been made. The general style of the work has been maintained and especial attention has been paid to the clinical aspect of the diseases, although their pathology has not been neglected.

The chapter on Angina Pectoris does not seem to have received the careful attention which has been devoted to

other parts of the book. The form of this affection known as "angina vasomotoria" is now generally recognised by most authorities as occurring more frequently than had hitherto been suspected and to be of considerable clinical interest. Only one page, however, is occupied with its consideration in this volume. The differential diagnosis of this variety has been shown to be of great importance and it is a matter of regret that a more lucid description is not given.

The subject of Aneurysm of the Arch of the Aorta, on the other hand, is fully discussed, although the treatment is given rather too briefly and the more modern methods of treatment, such as the injection of substances intended to increase the coagulative power of the blood, are not mentioned.

The Principles and Practice of Modern House Construction. Edited by G. LISTER SUTCLIFFE. In Two Volumes. London and Glasgow: the Gresham Publishing Company. 1899. Vol. I., pp. 503; Vol. II., pp. 512. Price 50*s*.

THIS important work has been issued in two handsome volumes which contain no less than 700 figures in the text as well as a series of separately printed plates. The staff of collaborateurs numbers 17 and includes the names of recognised authorities on sanitary science, medical men, chemists, and architects. "Construction," perhaps, has been dealt with at greater length and in greater detail than any other branch, but the subject is an exceedingly comprehensive one and the whole work opens our eyes to the remarkable number of pure science matters upon which the question of house construction hinges. Most of the contributions are written so as to be understood by the average householder, although it may be said that technicality is more obvious in those sections contributed by architects. There can be little doubt of the value of the volumes as a whole upon the wide field with which they deal. It is not easy to bring a contribution of this kind up to date considering the compilation which it entails. Nevertheless, in it will be found a broad and intelligible exposition of sanitary principles underlying hygienic house construction, and the various contributions are written completely in accordance with modern knowledge.

The general introduction is by Dr. F. W. Andrewes who contributes an interesting historical sketch of the growth of sanitary science. In this task he has been considerably assisted, as he acknowledges, by the writings of Sir John Simon. In these introductory chapters is defined in a clear and interesting manner the position of sanitation at the present time as compared with what it was in the past. Indeed, it is safe to say that attention was only given to this important aspect of public health with the dawn of the Victorian era. When this fact is borne in mind it will be readily understood what enormous and satisfactory progress has been made in the application of the principles of sanitary science. With the growth of knowledge of what constitutes sanitary environment and the application of this knowledge the improvement in the public health has kept corresponding pace. Although sanitary science is not as exact as is desirable in some particulars, especially in regard to the why and wherefore of well-known facts, still sanitarians have been guided correctly by practical experience in the absence of an exact knowledge of the causes of unhealthy conditions. At the present moment, for example, we possess no certain knowledge of the nature of the poisonous action of sewer air, but that sewer air predisposes to an unhealthy condition undermining the natural resistance of the body to unhealthy influences is a clear fact which experience has established. Dr. Andrewes says that it can hardly be supposed that when largely diluted after escaping into a house sewer air can owe its evil properties to its gross chemical composition. "Something more subtle than this must be at work, and it has been suggested that the organic matter present in it may contain an obscure chemical poison, possibly of an alkaloidal nature." We believe that this suggestion had its origin in the editorial columns of THE LANCET and we have seen nothing as yet which is opposed to such a suggestion. While on this subject Dr. Andrewes might with advantage have given a summary of the experiments conducted by the Italian investigator Dr. Alessi who showed that rats when exposed to sewer air were very susceptible to typhoid poisoning, while in the same series of experiments rats that had enjoyed fresh air seemed proof against the invasion of the typhoid bacillus even when it was inoculated subcutaneously. The remarks of Dr. Andrewes on disinfection and the disposal of refuse and other subjects should be of especial interest to those whose work relates to the structural points of houses.

In Section I., which follows the general introduction, Professor Robert Kerr, F.R.I.B.A., discusses the aspects of houses. Here he enters into general considerations, such as site, aspect, light and air, and style of plan. We note with pleasure that the author does not take quite the view of Bacon that "houses are built to live in and not look on," though from the point of view strictly of public health there is no doubt that efficiency of construction is more important than structural beauty. Professor Kerr keeps in view the sanitary requirements as well as the artistic effect. The succeeding article, which is devoted entirely to construction, is contributed by the editor and the information contained therein is of the most valuable kind and is worthy of perusal by all interested in the construction of houses; indeed, we have found that the writer refers to some very recent materials so that some good hints may be derived by architects and builders from this contribution.

The next subject dealt with is that of Water-supply, in Section III., by Mr. Henry Law, M.I.C.E., in which the sources of supply are considered and the best way of tapping them. This involves the important questions of the raising of water and its conveyance. Mr. Law concludes with a chapter on the purification of water in which he gives excellent practical details of the methods employed for the filtration of water and for softening water by well-known processes. Water-supply from the Domestic Point of View is the subject of the next section, by Mr. Henry Clay, and we find here the kind of information that is constantly in requisition and a description of the materials used for the pipes, the nature of joints, cocks, and taps, and the principles underlying the systems of hot-water supply. We are glad to find that Mr. Clay has not omitted to mention the dangers arising from boiler explosions. He fully describes the safety-valves which have been devised to avoid such contingencies and rightly lays stress on the importance of examining these valves from time to time. He concludes this section with a description of a mercury regulator which appears to us to be more convenient and reliable than other devices. The next section (Section V.) relates to household filters and is contributed by Dr. H. Jossé Johnson, who has conducted some excellent original inquiry on the subject. He refers to the Report on Filters and Other Water-purifying Agents by THE LANCET Sanitary Commission of 1867,[1] when of course the methods of testing a filter did not admit of the precision of the present day, bacteriology having now been brought to bear upon the subject. In regard to modern investigation he gives in one instance a wrong reference. The table which he reprints did not appear in THE LANCET, 1894, vol. ii.,

[1] THE LANCET, Jan. 12th (p. 53), March 23rd (p. 371), and July 6th (p. 13), 1867.

p. 1058, but it occurs in the paper communicated by Dr. Sims Woodhead and Dr. Cartwright Wood to the corresponding number of the *British Medical Journal*. We may say that these researches have thrown great light upon the question of domestic filtration. They practically showed that the bulk of domestic filters were worse than useless. Sections VI., VII., and VIII. inclusive relate to sanitary plumbing, sanitary fittings, and drainage. The last section of the volume (Section VIII.) contains an excellent chapter on the flushing, cleansing, and testing of drains.

The second volume opens with a chapter on Sewage Disposal by Mr. Percy Boulnois, in which we find a very fair synopsis of the methods of disposal past and present. The portion on Bacterial Methods might have been written at greater length considering the enormous advances that have recently been made in regard to the bacteriological disposal of sewage. This section is followed by Section X. on Warming, by Mr. E. R. Dolby, which contains a very useful account of proper and improper methods of heating. The author might with advantage have referred to THE LANCET Commission on Gas Heating. Section XI. deals with the same subject except that the warming and cooking methods described are effected by means of the electric current. Following this section is an admirable contribution on ventilation by one of the foremost exponents of the subject, Mr. William Henman, whose name is associated with the plenum system of ventilation introduced at the Birmingham New General Hospital, of which he was the architect. In succeeding sections lighting is dealt with in all its forms, candles, oils, and electricity, by Mr. A. Claremont; while Mr. Henry Clay adds a good account of modern methods of gas-lighting. In this account he refers to the report of THE LANCET Commission in January, 1895, upon the Welsbach burner. His conclusions are correctly based on these results but hardly in grammatical terms, an error which might appear to be due to the original Commission, but this is not the case. Indeed, the word *sic* placed in parenthesis after a verb in the singular which should be in the plural is evidently a query by the editor. Space not permitting even a passing reference to certain other sections connected with house construction we may pass on to chapter iv. of Section XVII. by the editor, on the Improvement of Existing Houses. In this chapter defective plumbing and drainage are dealt with and the editor acknowledges that he has taken advantage "of the valuable report (published in THE LANCET of July 4th, 1896) of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers' Work." The permission of the Editors of THE LANCET is also acknowledged in regard to the reproduction of certain plates which are illustrations of three typical houses containing almost as many sanitary defects as possible, with illustrations of the best way of removing these defects. We may state that an addendum to this work of our Commissioners has since appeared in our columns (March 4th, 1899) under the title of "Report of THE LANCET Special Commission on the Water-supply and Disposal of Sewage in Rural Districts," but of course this appeared too recently for useful abstraction in the present edition of the work under notice. The remaining sections refer to Climate and Situation, by Dr. E. F. Willoughby; Stables and Cow-houses, by Mr. F. W. Lockwood; and Sanitary Law, by Mr. A. Wynter Blyth. Mr. Wynter Blyth's contribution appears to be a simple compilation of statutory provisions in regard to the subjects within the province of public health.

This excellent production is one which merits congratulations on all sides. The staff of contributors comprises acknowledged authorities on the many subjects concerned and there are evidences throughout the pages of excellent editing, while the style of the volumes is attractive and very creditable to the publishers. No subject could be of more importance than modern house construction and it is surprising to find on reflection what a number of specific scientific subjects it involves. Hitherto, we believe, no literary work has been devoted exclusively and so comprehensively to the subject as is the one before us, and we are confident that it will be looked upon as the standard of reference.

Practical Gynæcology: a Handbook of the Diseases of Women. By HEYWOOD SMITH, M.A., M.D. Oxon. Second Edition. Revised and Enlarged. London: H. J. Glaisher. 1900. Cr. 8vo. Pp. 230. Price 5*s.* nett.

THIS is the second edition of a book the first edition of which appeared in 1877. After the lapse of so long a period of time as 23 years it may well be questioned whether it is worth while attempting to do anything short of completely re-writing a text-book, and most especially one dealing with a subject such as gynæcology, in which such enormous strides have been made in our knowledge during recent years. Dr. Heywood Smith says in his preface that these great advances have necessitated a thorough supervision of the text. Of this there can be no doubt; it remains to be seen whether or not this has been done to a sufficient extent. The book consists of a summary of the various gynæcological affections based upon the nomenclature of the Royal College of Physicians of London, and under each disease are given its definition, cause, symptoms, signs, diagnosis, prognosis, and treatment. Some of the definitions are good and sufficient, but others suffer from the brevity which is essential in a work of the kind. Thus, the definition of a mole as "a spoilt egg," although qualified by the statement that the life of the ovum is destroyed and that it is expelled as a shapeless mass, hardly conveys a correct idea of the pathology of this condition to the reader. The author lays a good deal of stress upon the results of "attempts at unimpregnated ovum development" as a cause of the formation of ovarian cysts. We are surprised to find that Dr. Heywood Smith apparently still endorses the recommendation of the late Dr. Protheroe Smith to prepare some patients for ovariotomy by a preliminary venesection. Such a practice is hardly likely to benefit a patient before what may be a difficult operation attended with a good deal of hæmorrhage, even if the pulse should be incompressible. There is evidence of want of care in the revision of the book and, upon the whole, the endeavour to bring it up to date cannot be said to have succeeded. No mention is to be found of pyosalpinx in the index, and all that is said about it in the text is "that inflammation of the oviduct may pass into abscess (pyosalpinx)." The term "puerperal fever" has been expunged from the Nomenclature of Diseases of the Royal College of Physicians of London, 1896, and yet both puerperal fever and puerperal septicæmia are described under separate headings as if they were separate and distinct diseases. If more care and trouble had been expended in really bringing the book up to date it might have fulfilled the wish of the author that it should serve as "a refresher for the busy general practitioner," but in its present form we are afraid it will hardly fulfil this function.

UNIVERSITY COLLEGE, BRISTOL.—The Associateship of University College, Bristol, has been conferred on Mr. William Marmaduke Bergin, M.B., L.R.C.P. Lond., M.R.C.S. Eng.

LONDON HOSPITAL MEDICAL COLLEGE. — The prizes and certificates will be distributed to the students and probationers this year on July 19th, at 3.30 P.M., in the library of the college by Mr. Frederick Treves, F.R.C.S. Eng., consulting surgeon to the hospital

THE LANCET.

LONDON: SATURDAY, JUNE 16, 1900.

SUNDAY, June 24th, is the day selected this year for the simultaneous appeal from all the London pulpits on behalf of the medical charities of the great metropolis. For 27 years this annual appeal has been made with results which we have recorded in our special supplements; and to the Supplement for 1900, which we publish to-day, we now refer our readers, begging them one and all to use their utmost influence that the Fund may continue to be the success that it has been; and more, that it may grow with the growing needs of the institutions which it has been designed to assist. We know that the interest of the medical profession in this great Fund is unabated, but we wish that the laymen into whose hands many of the supplements will pass would make some more vigorous attempt to realise that a great responsibility in the matter rests upon them. To us it seems impossible to read, nay, to glance at, the figures relating to the Metropolitan Hospital Sunday Fund, or to consider even superficially the various circumstances which have called that Fund into being, without feeling that every Londoner as a point of honour should tax himself to what point he is able to support the hospitals of London. London grows, but the Metropolitan Hospital Sunday Fund does not grow. The medical profession is hourly engaged in fighting a battle against sickness the burden of which is not properly shared by the citizens on whose behalf it is waged. London is apathetic in face of the needs of her hospitals, and her increase of wealth has not led her in any marked degree to attempt to place the charities to which she owes so much upon a firm financial basis. We do not ask any of our readers to take this for granted. We beg them to listen to the ministers of various denominations who will appeal on Hospital Sunday on behalf of the Fund and who will bear out every word that we say. Be it remembered that the ministers will know whereof they speak. They are fitted to testify to the stress under which the hospitals labour and to the good that they do both from their knowledge of the subject and from their association with the care of the sick that the ministerial office of every religion entails. We are certain that they with one accord will bear us out in saying that the Fund is badly supported and that the subscriptions should realise a much larger total.

Collectors are wanted for the Fund. Many persons only need to have their attention called to the claims of the Metropolitan Hospital Sunday Fund in order to subscribe liberally to it. But many more, for this reason or that, neglect the excellent opportunity of doing good. We beg accordingly to lay upon those who have themselves not forgotten the Fund the task of reminding others, some of whom only require that their duty should be brought before them at the right time and place and perhaps by the right person. A large number of subscribers will be urged to give when they attend Divine worship. The church, chapel, or synagogue with them will be the place, and the minister will be the person, who will persuade them. The Fund is primarily connected with a collection made in Christian places of worship on the first day of the week, but it omits no sect or religious denomination of the Christian or of any other religion from its appeal—just as the hospitals which it benefits exclude no sect or denomination or religion from their wards. There may be some who from the ritual connected with the religion which they profess will not hear the claims of the Fund urged from the pulpit. We ask them nevertheless to give their money and we urge their friends to see that they do not fail to give merely from forgetfulness. Again, there are many of those best qualified to give largely who, for divers reasons satisfactory to themselves, will not be in church, chapel, or other place of worship when the appeal is made. May we urge upon the relatives and friends of the absentees before whom these pages come to constitute themselves collectors for the Fund? It may be that some will not attend public worship or any place where public collection is made because they are ill; let them not therefore forget the hospitals, but let them rather be reminded where the skill was gained which they have called in to their aid. Let them remember the poor and think of the homes in which those poor live, of the risks to which they are exposed. Let them think in the light of their own pain of what the fate of these would be if they had no hospital to turn to in their need. It may be, on the other hand, that healthy exercise claims the absentees on the one day of the week which they can devote to it. Surely these of all others should not be allowed to forget. To the golfer and the cyclist no one grudges less than we do his game or his ride—the medical profession is no enemy to the habit of healthy exercise that is one of the most marked characteristics of our people—but we desire to recall to the memory of the strong and vigorous man as he hurries in pursuit of fresh air and pleasure that it is for the sick and maimed that we appeal on Hospital Sunday, and we ask him to tax himself a small portion of the amount that he annually spends in healthy enjoyment for the sake of those whose chance of health depends on the generosity of their fellow-men. At all events, let him not fail to give because he forgets. He should not forget, and if he does forget he should be reminded. And in expressing a hope that all who might not otherwise remember the Hospital Sunday Fund will be reminded of it by those to whose attention it is brought in the course of their Sunday worship we are appealing largely to women for coöperation and assistance. We do not wish to initiate "snowballs" of behalf of the Hospital Sunday Fund, but we feel sure that if every woman who may read our supplement were to remind all her friends and all whom she can influence how urgent the need is that they should contribute, and were to enlist all in her power to carry on the task of similarly reminding others, the Fund would be materially aided by the work so done.

The people of London, to whom primarily, though not wholly, we look for a response to our appeal, have done their

share nobly in subscribing to the various funds incident upon the South African war, and have also given largely to the Indian famine fund. Those interested in the management of the Metropolitan Hospital Sunday Fund cannot but feel a little apprehensive lest the fount of generosity, so freely drawn upon during the last eight months, should have begun to run dry before the hospitals have received the draught that to no small extent stands between them and starvation. Surely their anxiety is misplaced. We believe that everyone who has followed the events of the South African war—and who has not done his best to understand a matter of such national import?—will admit that the history furnishes forcible arguments for the maintenance of the hospitals of the country in a condition of complete efficiency. The praise which the Royal Army Medical Corps have won for themselves in the campaign, now it is hoped nearing its closing stage, by their skill, by their courage, and by their powers of organisation, is largely due to the training, scientific and disciplinary, received by the officers when studying at the big voluntary hospitals of the United Kingdom, and prominent among these hospitals are the hospitals of the metropolis. We trust that on Sunday, June 24th, congregations of London will listen to the appeal of their ministers on behalf of the Metropolitan Hospital Sunday Fund with a special predisposition to support to the best of their ability these noble charities, and we also trust that all who have an opportunity will press upon their friends the necessity of subscribing.

THE disciplinary action of the General Medical Council in theory is exercised in the November session, but in practice it is called for quite as much in the May session, for it would be unreasonable to keep accused persons in suspense for six months after the first meeting of the Council at which the charges could be investigated. The penal cases which occupied the attention of the Council at its recent meeting were nine in number and resulted in the removal of no less than five practitioners from the Registers—three from the Medical Register and two from the official roll of the dentists. It is always well to consider the offences for which the grave penalty of removal from the Register is inflicted, for they vary from session to session. We have hitherto been accustomed to regard "covering" as the commonest offence warranting suspension from medical practice. But it is noticeable that this was not the offence alleged against any one of the five practitioners whose names have just been erased. The offences were, respectively, (1) drunkenness, disorderly conduct on one occasion and on another assaulting and beating a female; (2) association with an Anglo-Australian institute which advertised publicly systems of medical treatment, the advertisements being in themselves discreditable to a British registered medical practitioner; (3) systematically seeking to attract professional practice by the issue of public advertisements advertising as a graduate in dental surgery in America without having visited America or undergoing any examination; (4) habitually publishing advertisements as R.D.S.E., thus implying connexion with one of the Royal Colleges; and (5) practising a fraud upon a gentleman by making out to him a bill for professional attendance on his wife, the attendance never having been given. We propose to consider some of the circumstances of these cases, though the names of those convicted of unprofessional conduct need not be given.

The offence of drunkenness may not appear to some a professional offence, and they may think it one for which a man is sufficiently punished by the magistrate in a police-court. For a single occasion that view would doubtless generally hold. But it is otherwise when the member of a responsible profession appears more than once in the police-court on such a charge, and especially so if at the end of six months he appears again before the General Medical Council without any obvious improvement in character and without adducing testimony from others to such improvement. It is clear that such a person should be removed from the Register of medical practitioners both for the advantage of the public and the good repute of the profession. Drunkenness is an offence in any man against the rules of society, but in a medical man it is to be severely condemned, because it may lead to terrible disasters in which the sick are the sufferers. We know the temptations offered by the irregular hours and hard work of practice, especially in country districts. But against these temptations every practitioner should be on his guard, and it is sad that even two gentlemen out of 34,000 should have to appear to answer such a charge. In the second case of the sort investigated the Council gave the practitioner time to consider and amend his ways. In the next three cases the offence consisted in advertising in such a manner as to constitute "infamous conduct in a professional respect." Here again the temptations are obvious—as obvious as those to drunkenness and as vulgar. What is and what is not legitimate or unavoidable publicity must often be a matter of doubt, but we do not think that anyone will accuse the General Medical Council of having acted, as a rule, with harshness. So far from straining to bring home to members of the profession the offence of advertising the tendency of the Council has been to be blind to the *lâches* of regular sinners. In the cases which it has now punished with erasure from the Register any other decision would have been ridiculous. It is significant that two of the offenders are dentists. Dentists hitherto have been allowed a licence with regard to advertisement much greater than that permitted to medical practitioners. But after seven years' notice the Council has by two erasures signified that this licence must not be counted upon any longer. Dentists who wish to retain their places in the Register will do well to restrict their advertisements to the mere announcement of their addresses or, better, to abstain from advertising. Then they will certainly be safe. The last case, that of the practitioner whose name was erased for making out a bill to a husband for an imaginary medical attendance on his wife, is unique. The offender's counsel argued that this was not infamous conduct in a professional respect because it was not done towards an actual patient or in the actual pursuit of professional work, but the Council took a different view, and it is not likely that its decision will be called in question.

In some respects the most interesting case brought before

the General Medical Council was that of the medical man who was summoned for employing an unqualified assistant whom, it was alleged, he permitted to attend on, and administer relief to, patients and carry on practice as if he were duly qualified. The complaint was brought by the Gateshead Medical Association and was supported by the Medical Defence Union. The interest in the case was complicated by the fact that differences existed between the accused and the other medical practitioners of his neighbourhood with reference to the rates of payment in certain medical clubs. An attempt was made to raise these rates and the medical man against whom the charge of "covering" was brought took the clubs at the old rate in reply to advertisement for a medical man. For a time he had a qualified assistant, but when the assistant left he could not get another with a qualification But he obtained assistance from an unqualified man, whom he said he regarded as a "pupil." The Council found the charge of "covering" proved, as it could not look on the assistant as a mere "pupil." It did not, however. proceed at once to remove the offender's name from the Register. The very delicate circumstances in which the case against him arose no doubt made the Council more careful in the exercise of its power, and its caution was wise. It would be a most unfortunate thing if the penal powers of the Council were ever suspected of being exercised in response to professional misunderstandings. The Gateshead Medical Association was well-advised in bringing the case before the Council and it is probable that the offence will cease.

One circumstance should be noted before closing this brief commentary upon the disciplinary action of the General Medical Council. In all the cases where the offender's name was removed from the Register the Council acted upon its own initiative. There had been no previous action by any of the medical bodies whose diplomas were held by the accused persons, a circumstance which, considering the glaring nature of some of the offences, is not a little surprising.

IF there is one class of human beings more than another whose infirmity is to be considered with reverence and apart from all considerations of mere gain it is the insane, while those whose condition borders on insanity are almost as much to be commiserated. And in either case where the social position is one of poverty the sadness is much enhanced. It is therefore most humiliating to learn that in one of the great central parishes of London, where we might have expected to find enlightened administration, there has been brought to light a system of dealing with the insane which is discreditable alike to the guardians, to their officers, and, we are sorry to say, to certain members of the medical profession.

On June 7th a report was presented to the St. Pancras Board of Guardians by Mr. F. PURCHASE, chairman of the Relief Committee, which made certain very definite allegations against the relieving officers in connexion with the certification and admission of lunatics to licensed houses. Mr. PURCHASE said that of the guinea fee received by some of the medical men called in by the justices to assist in the examination of persons of unsound mind the relieving officers got 5*s*. and varying sums of 1*s*. and upwards from other medical men. The relieving officers admitted that this was the case, while it appeared that those medical men who had refused to give presents had been boycotted and received no cases. The report also stated that nearly all the pauper lunatics from St. Pancras had been sent to two private asylums to which the Board paid something over £12,000 a year. These two houses, Hoxton House and Bethnal House, had, it would seem, charged the St. Pancras Board of Guardians 2 guineas per patient per week, while other parishes were only charged 19*s*. 3*d*. per patient; so that St. Pancras had been paying more than four times as much as would have been the case had the patients been sent to the county asylum, where the charge was 9*s*. 11*d*. per patient. The relieving officers admitted receiving sums varying from £2 to 10*s*. for each patient from the officials of these two private asylums The report also called attention to the remarkable fact that St. Pancras pauper lunatics numbered 1600, while in Islington, a larger parish, the number was only just over 1000.

It is impossible to comment without indignation on a course of behaviour so wrong in principle, so cruel to the patients, and so unjust to the ratepayers; while it is equally impossible to offer any excuse for the medical men who, by the confession of the relieving officers, have allowed themselves to be involved in it. We can only hope that a flat contradiction may be forthcoming from some at least of them. It is amazing to think of the extent to which bribery has been carried out and the tardy exposure is not creditable to the vigilance of the board of guardians, although it must be admitted that when Mr. PURCHASE'S committee spoke it spoke with no uncertain voice. We are told plainly by Mr. PURCHASE that nearly all the pauper lunatics from St. Pancras were sent to two private lunatic asylums at improperly high prices. The proprietors of these asylums have, we presume, some explanation to offer, and we would urge them to reply to the charges brought against them, and widely circulated by the press, without delay. The hoary nature of the abuses that have just been brought to light cannot be alleged in extenuation. The scandals have confessedly been going on for 30 years and it is conceivable that the present generation of officers have learnt to throw the responsibility on their predecessors. If this is the only excuse we may say at once that it is a totally inadequate one. Things that were culpable 30 years ago are more so now. Otherwise we should be going backward in public and municipal morality instead of forward. That medical men should have been implicated in such grave charges, even though their share is only passive acquiescence, is lamentable, but we withhold censure till it is obvious that the time for explanation has gone by. In the meantime we say that the charges call for reply. The remuneration of professional work among the poorer classes is, we know, inadequate and the system of gratuitous advice is so demoralisingly extensive as to make members of our profession less independent than they should be, but these facts would not constitute excuses for the condition of things that is alleged by the Relief

Committee of the St. Pancras Guardians to prevail in St. Pancras. Guardians everywhere must look into the matter. The scandal calls for a thorough examination into the methods under which pauper lunatics are certified. A very limited experience of pauper lunacy is enough to show that much of it is not grave or organic, so that there is every reason why all cases should be investigated by persons above suspicion and should be intrusted to the treatment of independent and disinterested practitioners.

Annotations.

"Ne quid nimis."

THE ALDERSHOT FIELD DAY.

WHATEVER might have been the opinion entertained of the late military operations at Aldershot from a military or spectacular point of view we think that the results from a humanitarian or medical one must be regarded as lamentable. Monday, June 11th, was, as everybody will recollect, an exceptionally hot and oppressive day. The thermometer, sheltered from the direct rays of the sun, rose to 89° F. and exposed to them to 116°. The troops, numbering nearly 30,000 in all, were under arms for eight hours; they were improperly clad for such hot weather and insufficiently fed before starting for an unusually trying field day which, in point of fact, should not have been undertaken under the circumstances. The men fell out in all directions on the homeward march in consequence of the heat, fatigue, and distress which they had undergone; four of them died from heat-stroke and a considerable number had to be admitted into hospital—all suffering more or less, and some dangerously, from heat-exhaustion. Such are the facts briefly stated, and it seems surprising, with all the past experience which the military authorities have had of field days, marches, and manœuvres in and around Aldershot, that the arrangements for such occasions should not be about as perfect as they can be practically made. No one could, of course, have predicted when the day was fixed upon that it would turn out such an exceptionally hot and unfavourable one for the purpose. It is easy to be wise after the event, and had these untoward occurrences been foreseen the field day would, no doubt, even at the last moment, have been postponed or the time occupied by the military operations would have been curtailed. But there seems to be still a good deal lacking in the system and method adopted on such occasions. Why should our soldiers be exposed to any needless risk of life, distress, and suffering which can be avoided by common-sense and hygienic precautions, such as suitable clothing, protection of the head by light helmets of a suitable kind, the provision of a good meal before starting, with light refreshment at halting-places, and the plentiful supply of watercarts all along the route? It seems to us that there might be some standing regulations specially framed for hot-weather marching and field days such as could be followed on all occasions of this kind. We know, of course, the argument so frequently put forward, that soldiers have to undertake all this and much more in time of war, but it seems to be forgotten that in a campaign they have usually gone through a course of preparatory training beforehand, that they are also properly clad and equipped for the work in hand, and that they are stimulated by military ardour as well as by the fact that they are acting under some paramount or recognised military necessity. A wise commander does not, if he can help it, land his troops or his horses from shipboard in a hot climate and at once start them, whilst still "soft," on a long and trying march.

THE METROPOLITAN HOSPITAL SUNDAY FUND: APPEAL IN THE CITY.

THE Rev. Harry Jones, Rector of St. Vedast, Foster-lane, Cheapside, E.C., who in many practical ways has shown his interest in the Metropolitan Hospital Sunday Fund, has had printed a circular letter for use by himself in place of the circular letter issued by the Metropolitan Hospital Fund for the purpose of reaching those people who are absent from church on Hospital Sunday. The letter is as follows:

DEAR ——,—If you should be absent from town, or be present in no place of worship on or near Sunday, the 24th June, forgive me for reminding you that aid will be then asked throughout the metropolis towards the support of its great hospitals. This appeal has no exclusive connexion with church or chapel, but relies upon the goodwill of those who appreciate hospitals as schools of medicine and centres of cure, especially in case of accidents, when ready help is needed by any sufferer, and most often by those who are poor. Should you then be disposed to join in a corporate effort (all the more encouraging because it is simultaneous) to meet wants supplied by hospitals, will you send me something, however small the sum, which will be acknowledged promptly, and paid into the Lord Mayor's Hospital Sunday Fund at the Mansion House?

In the City, where few influential people attend a church on Sunday, except St. Paul's Cathedral, the letter should prove most useful to ministers. We understand that the letters are printed by Messrs. Collingridge, 148, Aldersgate-street (the office of the *City Press*), who keep the type "standing."

CEREBRAL AND MENTAL DEGENERATIONS ATTRIBUTABLE TO THE USE OF OPIUM IN INFANCY.

DR. T. D. CROTHERS, superintendent of the Walnut Lodge Hospital at Hartford, Connecticut, U.S.A., has an interesting report in the *Journal of the American Medical Association*, May 19th, 1900, of cases illustrating the cerebral and mental degenerations observable in adult life owing to the injudicious use of opium in childhood. The danger of opium as a remedy in infancy has only recently been recognised. The widespread use of proprietary medicines containing opium as soothing syrups for children has resulted in injuries observed later in life which could be distinctly traced to the deleterious effects of the opium. In children, as in adults, the same initial exhilaration (or excitement) followed by depression results from the use of opium, and in children or adults of fine nervous organisation a smaller dose produces the same effect, which in those of coarser organisation can only be produced by a larger dose. The power of resistance to the drug is very small in the child and the frequent use of the drug produces characteristic cerebral and mental degenerations. Opium given in convulsions, intestinal troubles, insomnia, and nervous irritations may often give temporary relief, but if its use be continued it may produce lasting mischief. A lessened vigour of intelligence with a weakness of volitional power amounting even to stupor, may result, together with loss of self-control and a proneness to morbid impulses. Disorders of digestion are also a common result. The following clinical accounts are instructive and teach important lessons which should not be disregarded. In a family of four children of healthy parentage, one, a boy, was dull, passionate, and of low intellectual grade. He would over-eat and drink to excess anything he fancied. He was stupid and obstinate and at times excessively irritable. "No one in the family resembled him in any way, but all were healthy and vigorous in mind and body. When one year old he had a convulsion

and was given opium daily for over a year, then at longer intervals, and finally it was abandoned. The parents noticed it was affecting him at the time, changing his mind and habits, and would not permit its use again." Here was an example of retarded brain growth with perversion of mental function, which in later life would probably tend to some form of mental disease or dementia. In a second healthy family one son became an impulsive inebriate at the age of 18 years. The other children in the same surroundings and conditions of living were temperate and well. During infancy this boy was treated with morphia for intestinal troubles. At one time it was thus taken for nearly a year by advice of a physician. "He was dull and stupid much of the time this was taken, and its use as a medicine was continued for years after." The boy soon after the age of puberty began to drink spirits to excess and was now a periodic inebriate. Another interesting case was that of two children of a family, one a young woman who at the age of 24 years suddenly became addicted to opium and alcoholic excess and showed much mental disturbance. "During infancy she was nursed by a Hindoo woman, and was noted for her stupor and tendency to sleep. In childhood she was extremely nervous and suffered from many hysterical affections. ..... Her brother, born two years later, was nursed by the same woman, and was noted for his somnolence and general stupor during this time. Later it was found that the nurse was an opium taker, and that both children had been under the influence of opium from nursing. The boy grew up exceedingly nervous and irritable. At one time he drank to excess and was a gambler. He was changeable and notional, became a clergyman, then a physician, and finally a speculator. He is now an opium taker and neurasthenic, an invalid not 30 years of age." Two other children of this family, one born before this Hindoo woman was taken as nurse and the other after she was discharged, were strong and healthy and free from any peculiarities, mental or bodily. Other interesting cases are recorded, and Dr. Crothers concludes as follows: "The ignorant mother who uses soothing syrups freely to suppress the irritation of the infant is not the only offender. The routine and often thoughtless physician who uses opium freely in infantile prescriptions is responsible in many cases for the wrecks of later life."

THE TRANSPORTATION OF DEAD BODIES.

AMONG the Acts of the Legislature of New Jersey, U.S.A., passed during its latest session we note one which is a good example of the practical interest in sanitary questions displayed by our cousins across the Atlantic, and which, moreover, suggests a possible useful addition to our own public health legislation. It is "an Act concerning the transportation of dead human bodies across or within" the State of New Jersey, and it deals with dead bodies in two classes. In the first place, it forbids any undertaker or other person to consign, or any railroad or common carrier to convey, across or within the State any human body dead from small-pox, Asiatic cholera, yellow fever, typhus fever, or bubonic plague, except in a hermetically sealed casket and except a license for such transportation be first obtained in writing from the board of health of the State or from one of its officers or inspectors. In the second place it forbids the transportation within the State of New Jersey of bodies dead from other causes than those enumerated, except under conditions which include signed certificates in duplicate from the physician who has attended the deceased in his last illness or from "some other practising physician in good and regular standing." This certificate must fully and minutely identify the body and set out the cause of death and further certificates from the undertaker charged with removing it must state numerous other particulars with regard to its removal. If these formalities are duly complied with a permit for the transportation of the body will be issued. In England the need for such precautions does not arise so often as on a continent where a body may be brought home for interment from a State within or without the Union over thousands of miles of railway, and possibly in tropical heat, while the difficulty thrown by continental legislatures in the way of transporting dead bodies to a great extent prevents their frequent arrival on our shores from abroad. It does not, however, follow that no system should be observed in such cases or that no danger may arise which our Public Health Acts ought to be competent to prevent. Our Acts, as far as they treat of burial, are chiefly concerned with the procedure in cases where the relatives of the deceased will not do their duty. A body dead from an infectious disease may not, for example, be left uninterred for more than 48 hours except in a mortuary or room not used for living or working in, and there are legal penalties for conveying such a body in a public conveyance without notifying the cause of death to the owner of the conveyance. We know of no direct legislative enactment that systematically either prevents or materially hinders the possible transportation of bodies under conditions highly dangerous to the public should relatives capable of paying for their conveyance desire to inter them at a distance from the place of death and should those undertaking the duty of removal and interment be careless or incompetent. We note with interest the recognition in the New Jersey Act of the "practising physician in good and regular standing."

THE MANCHESTER AND SALFORD HOSPITALS INQUIRY ASSOCIATION.

TOWARDS the end of the year 1897 the Manchester Medical Guild through its council issued a circular to medical practitioners in Manchester and the neighbourhood upon the subjects of hospital reform and medical aid. With regard to the first subject the circular pointed out that a joint committee representative of the medical charities and medical societies of Manchester and Salford had been appointed to make inquiries.[1] The committee in question has just issued its report with its findings and recommendations which are as follows:—

The Association find:—I. That a considerable amount of abuse of hospital charity exists—i.e., that persons receive the service of hospitals who are not proper subjects for charitable relief. II. That the following appear to be the principal causes of this abuse:—(*a*) the insufficiency of the means taken to investigate the circumstances of patients applying for relief; (*b*) the necessity under present conditions for hospitals to show a large return of work done, as estimated by the number of patients and consultations; (*c*) the tendency of hospitals during recent years to accept trivial cases as suitable subjects for continuous treatment; (*d*) the custom at some special hospitals of treating cases that do not strictly come within the recognised scope of their work.

The sub-committee therefore strongly recommend:—That with a view to terminating the abuses which undoubtedly exist a conference of representatives from all the hospitals of Manchester and Salford be held, with authority either to create a United Hospitals Board for Manchester and Salford or to deal specially with the causes of hospital abuse, as set out in this Report and to discuss the acceptance of contributions by patients.

The most important of these causes are undoubtedly (*a*) and (*b*). Advertisement is the physical life and the spiritual death of nearly every department of the modern body politic. That is to say, everything is run with an idea of making it pay instead of, as should be the case, giving the best work. The ideal is not always attained, but whether it is building a

THE LANCET

SPECIAL SUPPLEMENT

IN SUPPORT OF THE

METROPOLITAN HOSPITAL SUNDAY FUND

Published in aid of the Appeal to be made on Sunday, June 24th, 1900.

IF " 'tis hard to lend fresh interest to a twice-told tale " the difficulty is presumably increased more than seven-fold where the tale is told for the fifteenth time, and is not lessened where the subject of it has been before the public for well-nigh twenty years, and has therefore begun to be regarded by the majority of Londoners as an annual event which, during the period covered by their memories, has followed Easter as surely as the recurring London season. This year, however, the claim of the Hospital Sunday Fund upon the benevolence of the public in London and everywhere else in the kingdom needs to be urged by us and by all interested in it with special insistence owing to a special circumstance. This circumstance, which, as we hope to show, strengthens the claim of the hospitals to the support of Englishmen, rich and poor, and which may aid us in pressing home that claim, at the same time may well lead to a call of annual and ordinary recurrence being forgotten or ignored in the year 1900 by some who have recognised its urgency on former occasions. The war is an absorbing topic; no one in these islands can fail to have his or her thoughts and conversation almost constantly occupied by it and its thrilling incidents, to the exclusion of other matters, among which must be counted the Hospital Sunday Fund.

The Hospitals and the War.

We are not only concerned by the fact that our fellow subjects think of the war and talk of the war, greatly to the exclusion of other topics, but it must be remembered that we are pleading the cause of charity as embodied in the Hospital Sunday Fund; and we cannot disguise from ourselves the fact that the war has already during the past eight months evoked in the cause of charity one of the most remarkable outpourings of the resources of rich and poor that the world has ever seen. It is still early to judge what the effect of this may be upon the incomes of institutions for the benefit of a poor that is always with us, and we trust that in a nation so patriotic, so earnest, and so wealthy as ours it may be small; but we cannot ignore the possibility that it may be considerable. Nor can we disregard the fact that in order to meet the expenses of the war taxation has been increased, and may be still further augmented; while in time of war although some trades flourish others suffer heavily, and a large number of our fellow-citizens are poorer than in times of universal peace. The generosity with which money has been contributed on behalf of the sufferers from famine in India and the financial situation which has arisen in consequence mainly of the state of the coal-market, are elements which may well combine to increase the anxiety of those interested in our hospitals, whether generally or in connexion with the special appeal about to be made; but the main feature of the present year, the one which does in the present and will presumably in the future render all other features of the year 1900 blurred and insignificant in comparison with its own prominence, is the war in South Africa, of which the full cost has yet to be reckoned. *And yet the war should be the hospitals' friend and advocate.* Great is the attention it has called to all branches of our military service, great is the improvement which is expected to result some day to many of those branches from the strain to which they have been subjected before the eyes of the nation and the world. The fierce light of the African sun and the glare of the battlefield have shown many weak spots in our armour of offence and defence. The keen eye of the critic at home and abroad has been cast upon those weak spots, and his tongue and pen have not spared them or those responsible for them. But for one portion of our war equipment, for a portion, literally, of vital import, in that it directly concerns men's lives, there has been unqualified praise. Criticism there may have been, of the kind that begets improvement in the future where good work has been done in the past; but taking it all round we challenge the world to affirm that the Royal Army Medical Corps has not brilliantly distinguished itself in South Africa, eclipsing all previous records of its own work, and of work done in the armies of other countries in recent warfare. We do not speak here of the bravery of the medical officer who attends the sufferer on the battlefield or remind our readers of individual names written in the roll of heroes who have died by shot and shell or by disease, struggling to save others' lives or lessen others' pain. They will, we feel sure, be remembered with other right gallant men who have died, by many of those who contribute of their wealth or of their poverty to the Hospital Sunday Fund; but for the moment we are appealing not so much to the enthusiasm as to the reason of our readers. The credit won by members of the Royal Army Medical Corps in South Africa, for themselves as individuals and for the distinguished body of which they are members, by acts of personal heroism and self-sacrifice, has been won by the display of the same qualities that many soldiers have displayed before, and that the Queen's subjects, in whatever capacity they may serve, are ever ready to display. The Corps has made its great success in the South African campaign by splendid attention to duty. In spite of the nature of the country in which our actions have been fought and of the sad fact that those actions have not always been fought successfully, and in spite of the terrible difficulties of transport entailed by infinitely drawn out lines of communication, battlefields have never been so quickly stripped of their wounded in the history of man, nor have the

wounded been so promptly cared for, so suitably sheltered, or restored to health in such high ratios. All this has been due to the completeness of the organisation of the Royal Army Medical Corps for bringing wounded and diseased under curative treatment, and to the recent advances made by surgery and medicine through the unwearying labours of the profession of which the Corps forms a branch.

It may sound like a platitude to say that our medical officers in Africa would not have been so successful in dealing with the wounds caused by Mauser bullet and Pom-Pom shell, or with the ravages of enteric fever or dysentery, if they had not had a good education in medicine at some time previous to their departure to the seat of war. It is, however, a platitude upon which we lay some stress even in the simple form in which we put it forward. We are writing to-day, not for the medical profession alone, but also for laymen possibly with friends at the seat of war, and we add a second platitude for their benefit on a point many who are able, and who should be willing, to subscribe liberally, who do not do their plain duty by hospitals, but who think of them merely as places to which dirty people are taken when they are run over in the streets. They wholly forget their obligation to the hospitals when they pay a fee to their medical adviser, feeling proud to be of those who can afford to recompense him for his attendance. It is to these that we point out with emphasis that the highest skill which money can place at their disposal is precisely the skill which owes its existence to the hospital ward in which it was acquired. Is it a rich woman, who a stranger to the accidents and illnesses of her poorer sisters, is about to become a mother and who must inevitably before long need medical aid? If any unforeseen and unusual complication arises in her case, and if it is treated with the same certainty and readiness as if the condition had been expected, this will be because the physician attending her has in his mind the lessons taught by hundreds of cases

STATISTICS OF HOSPITAL WORK IN LONDON DURING THE YEAR 1899.

* We reproduce the term "General Hospitals" as employed by the Council of the Metropolitan Hospital Sunday Fund.

of detail which it is just possible that they might otherwise forget. It is to the effect that the good education referred to could have been obtained in no other way had there been no hospitals at which to seek it. It was in the great hospitals which are maintained in all parts of our beloved Queen's dominions by the open-handed charity of her subjects, and more particularly in those great hospitals of London in whose behalf we plead to-day, that the skill was acquired which is saving the lives of thousands in South Africa. It is by the discoveries that have rewarded labour and research in these and similar institutions that medical knowledge has attained to its present position. We may seem to our professional readers to labour the point by discussing it further, but we are not sure that to all of them it is as abundantly clear as it is to us that the education of the medical man, as he now is, would be an impossibility, and that his science could never have reached its present point but for hospitals. This page will fall into the hands of dealt with in hospitals. This is equally so whether the medical man is obstetric physician to a hospital or whether he is relying on the record of observations made by hospital officers for the benefit of those studying under them, and for the medical world at large. We need not multiply examples; the truth is obvious.

Many will read these pages, and into whatever hands they fall many of those hands will have been pressed by hands now far away on the veldts and kopjes of the enemy's country; many of the eyes that scan these lines will have been dimmed with tears at the thought of the suffering or death of someone loved, and very few indeed will not be able to call to mind someone with whom he or she is acquainted and who has been during the past months in close daily peril of wound or disease. To the men and women of this great metropolis we appeal, and to the men and women of this great country, to remember their brethren who have fought in Africa in a climate exposing them to deadly disease, against an enemy armed with weapons of precision said to be superior to our own.

They must rely on medical aid when the disease strikes them down or the bullet flies true. It is for the institutions that have trained many of those who are giving this medical aid that we appeal, and not only that the hospitals may gain by any sense of gratitude aroused, but because there is danger that owing to the war the hospitals may actually suffer heavy loss.

May we remind our present readers that when it became apparent that the Royal Army Medical Corps would be overstrained in point of numbers by the call made upon it, and when it was, moreover, thought advisable to enlist the services of well-known civilian consulting surgeons, that there was one source only from which the auxiliaries needed could be drawn. That source was the hospitals. It was not to the extent or remunerative character of their private practices that Sir William MacCormac and Mr. Frederick Treves and their colleagues owed the fact that they were selected to proceed to South Africa, but to the reputation they had earned and to the skill they had acquired in dealing with deadly injury in our great London hospitals—in hospitals situated in the midst of a crowded poor population, where serious injury to body and limb and the operations entailed thereby are matters of daily recurrence, and where all possible facilities for observation and record as well as for operative performance are provided. Nor was it with regard to their private practices that any of the small band of able medical men who have worked or are working with our forces in South Africa were chosen. They were chosen because of the work which they had done and the experience

they had acquired in the hospitals for which we appeal to-day. And be it remembered that in the hospitals in which our surgeons, military and civil, now in South Africa began their professional education they acquired at an early stage of their careers more than professional skill. There they first gained knowledge of the value of organisation where life-saving has to be done on a large scale, and while learning the value of organisation learnt also by observation how to organise. There they first knew the value of discipline in such institutions and learnt how to enforce it, or to obey it, as the occasion might demand. The men who have attended our sick and wounded abroad have gained in their hospitals at home the *esprit de corps*, the honourable traditions, the habit of instinctive devotion to duty which alone could have enabled them to earn the praise which they have earned in appeal to rich and to poor equally. The letters of private and officer alike have spoken of the treatment all ranks have received when sick and wounded. We ask those who have received such letters to remember that every contribution to the Hospital Sunday Fund, however small, helps to swell its total, and that someone among their friends may have forgotten the claim of the hospitals and of Hospital Sunday who, however poor, might yet be grateful for being opportunely reminded. We want cheerful givers to the Fund and importunate beggars for it.

State-aided and Rate-aided Hospitals and Voluntary Hospitals.

Is the need so urgent? it may be asked by many. Undoubtedly it is. It may safely be said of almost every great hospital in London that were it a commercial concern,

our hospitals on the field and at the base alike. We ask our readers also not to forget the devoted women who have aided them in their work, who also have acquired their knowledge and skill, their discipline and their devotion to duty, in hospitals in London and elsewhere; who, whatever toil they may have encountered in the years of their training and of their employment at home, have cheerfully encountered ten times that toil amid the hardships, anxieties, and dangers of the campaign.

Let us say again, in case we may not have said it plainly enough already, that any appeal on behalf of our hospitals on the ground of the good work done in the war is an conducted for the sake of profit by those responsible for its solvency, or by men whose personal reputation as respectable members of society depended on the pecuniary prosperity of the institutions governed by them and associated with their names, it would have either to close its doors or cut down its expenses until an income was assured to it very greatly exceeding that which it at present enjoys. But to diminish the outlay of a hospital and cut down its expenses means to close wards, now perhaps crowded; and to turn away applicants waiting until beds may be ready for them means the loss to many sufferers of a last hope of health and strength. So the hospitals struggle on, living

from hand to mouth, relying on the splendid generosity of the wealthy and the smaller but no less generous and welcome contributions of all citizens who may come to their aid.

And those to whom such a story of poverty as this is told may ask another question. They may say, Is there no waste, no avoidable loss either in the administration of the Fund to which you ask us to give, or in the management of the hospitals in support of which the Fund is raised? To this we answer that it is as an administrative and economising agency that the Metropolitan Hospital Sunday Fund has achieved its greatest success. Among suggestions made from time to time with a view to better economic arrangements in our hospitals that of a Central Board has had many supporters. No such board as yet exists, but the council of the Metropolitan Hospital Sunday Fund has been in a position to accomplish much that those who urge the need of a Central Board demand, by its own suggestions and criticism made in the interests of coöperation and methodical administration among the various charitable institutions for the London sick. In distributing the funds annually at its disposal the Council has been able to exercise a gentle but not ineffective supervision over hospital expenditure, and to aid in enforcing upon each institution the doctrine that every pound of expenditure must be represented by its equivalent in the form of service or necessaries supplied to the objects which the revenue of the institution is intended to benefit. It will be remembered that when, in the Diamond Jubilee year, 1897, the Prince of Wales selected the London hospitals as the special objects to be benefited by those who sought to commemorate by their generosity the long reign of our revered and beloved Queen, it was to the Metropolitan Hospital Sunday Fund that His Royal Highness (acting, no doubt, under the best advice obtainable) turned for assistance and coöperation in regulating and organising the distribution of the resources placed at his command.

Some may say this year, as many on former occasions have said:—You ask us again to help to place the London hospitals upon a sound financial basis by charity, whereas, if they were the national institutions which you claim them to be, they should be aided from State or municipal funds. Look at the sum which a half-penny on the income tax would realise for them, or, if the rates should be selected to bear what must in the main be a metropolitan burden, consider that a penny in the pound is reckoned to be the rate that will supply the district voting for it with a free library. What is a free library compared with a hospital? Would not a far higher rate be cheerfully paid for the sake of placing these great charities upon a sound footing? Our answer is that it is precisely because these noble institutions are charities that we resist the suggestion that they should depend on incomes paid to them by State or city under the compulsion of Acts of Parliament. In their origin and throughout their existence they have represented the generosity of those that have towards those that have not, and we would not deprive the former of a single opportunity of showing sympathy for their poorer brethren; nor would we have those poorer brethren receive their help in trouble from any other source than the loving charity of those who feel for others in affliction. The question, be it moreover remembered, is one of substituting State or municipal aid for the incomes of hospitals not already derived from fixed sources, rather than of supplementing from public funds the charitable donations already received. We mean that if State or municipal aid was introduced to ever so small an extent a complete change of the whole system would follow inevitably in due time. Those who found themselves taxed for the hospitals would gradually cease to subscribe voluntarily, some because they would not care, or could not afford, to pay twice over; others because they would think that their subscriptions were not needed for a State-aided institution; and others because they would hold that the State or the municipality ought to do thoroughly, and bear the whole cost of, that which it did in part and over which it exercised control. With regard to this latter point it can hardly be denied that where the public supplied the funds it would expect to have a voice in the spending of them. Thus, instead of institutions ruling themselves independently through their wisest and most experienced members we should have branches of a Government department aided by local municipal wisdom directing the internal affairs of our hospitals. We cannot believe that we should see better hospital administration under such a rule, and we should soon expect to hear of a shower of legacies and donations falling to the London School Board as to see charitable benefactions continue in such circumstances. The name, by the way, of the School Board reminds us that the schools which the Board maintains from the rates are open to all children whose parents choose to send them thither without questions being asked as to the parents' means. We submit that those compelled to support the hospitals would in like manner expect the hospitals to be open to them. We do not, as matters stand, find that there is any great bashfulness in seeking aid from hospitals on the part of many who are not fit objects of charity and who could well afford to employ and pay their own medical men, and any innovation likely to foster this abuse must. in the interests of rich and poor alike, be wrong.

The present income required by hospitals affords no criterion of what hospitals would require to support them did they cease to be charities. We note, on reference to Mulhall's Dictionary of Statistics, that in Paris, where the State subvention to hospitals is put at £358,000 annually, the number of beds provided for 10,000 of the population is computed to be 41, whereas for London it is given as 18. We heartily wish that the proportion of beds provided for the London suffering poor might come nearer to that of Paris; but we would see it made to approximate, not under the compulsion of the law by taxing the whole or some already burdened portion of the community, but by the charity and benevolence of rich and poor moved to more universal recognition of the greatness of the hospitals' need and of the nobleness of the institutions that they are asked to assist.

Rich and Poor Alike Should Give: A Tax on Pleasure.

In asking for more universal support for the Hospital Sunday Fund we are influenced by the last balance-sheet of the Fund and the table[1] often placed before our readers which gives the sums that have hitherto been subscribed to it, distinguishing the amount received at places of worship from the "donations" which represent the larger gifts of the wealthy and comparatively few. On comparing the figures of last year with those of previous occasions it will be noticed that last year was distinctly a good year for the Fund. The total collected was £53,504, an aggregate larger than that of any previous year save 1895, when the sum reached was £60,361. Last year, however, as in 1895, the fact that the total stood out above previous totals was due, not so much to any notable increase in the gifts of the many, but to the fact that the generosity of the donors outside those subscribing in places of worship rose to an unusually high pitch. In 1895, out of the splendid total of £60,361, nearly £22,000 were privately given, and in 1899, out of £53,504, the individual donations came to over £15,000. A glance at the notes appended to the table that gives the progress of the Metropolitan Hospital Sunday Fund will prove to how few the Fund has to turn when expressing its gratitude for these princely gifts, and as a natural consequence with how little certainty the continued magnitude of such donations can be reckoned upon. Few can be expected to vie with Sir Savile Crossley in subscribing sums of a thousand or five hundred pounds annually; the note to the year 1891 shows that out of donations of £9019 a sum of £5000 came from the late Duke of Cleveland; while in 1895 the £21,990 given as donations included £10,000 from the late Mr. B. Barnato and his friends, £3400 from the Stock Exchange, and three separate gifts of £1000, of which one, like the £10,000 and the £3400, came from a source largely affected by the present situation in South Africa. There was no South African boom last year, yet £15,000 were given in donations, so that we must hope that in 1900, in spite of their liberality to the war funds and to the funds in aid of the famine- and plague-stricken population of India, the wealthy will not forget the hospitals at home. When, however, we point to the increase of donations as distinct from collections in places of worship as largely accounting for the increase of the Fund in certain years our object is to urge the general giver to increase that portion of the Fund which must be looked upon as constituting its more or less fixed income. For there must be but a limited supply of donors of the quality of those we have mentioned and of the late Dr. James Wakley.

Last year £38,194 represented the generosity of the general public, a body which in 1898 gave £36,532, in 1897 £37,396,

[1] See previous Hospital Sunday Fund supplements.

and in 1896 £40,501. Last year, therefore, although the gross total was the second highest on record, the gifts of the general public only exceeded the average of the three preceding years by £50. But if the general public were to raise its subscription to £40,000 as a normal figure, even this would only represent twopence halfpenny a head levied on a population of 3,840,000. Now the population of London numbers about 4,500,000, or considerably more than 3,840,000, even after the deduction from it of the "submerged tenth" which may be taken as incapable of subscribing anything. The hospitals are designed for the reception and succour of the poor, a class which admittedly includes many besides the "submerged tenth," but we can see no reason why the gratitude of the working man for the aid afforded to him and his in time of sickness or injury should not take a concrete form, implying that he is too independent to accept charity and offer nothing in return. To the working poor, therefore, we suggest that a gift which represents an economy of less than a farthing a month for each member of the family is hardly an impossibility. Nor would it represent an excessive or disproportionate gratitude for those benefits which the giver may himself some day receive at the hands of the hospital, and which hundreds of his fellow men and women of the working class receive daily. There are more ways than one, we admit, of looking at the subscription of a working man to a charitable object. Many will say that a shilling a year for a poor man with a wife and two or three children (each member of the family being represented by 2½d.) is an excessive amount, too much for any reasonable person to expect. In a measure this may be true, and we do not say that we expect to find subscriptions to the Hospital Sunday Fund from working men on such a scale; but at the same time, when we suggest a shilling once a year we cannot help fancying that the average working man, even with a family dependent on him, does not regard a shilling as an excessive amount to spend on beer in a single week, for it will be remembered that our calculation eliminates more than three quarters of a million of the poorest part of the population altogether.

Still, in fixing on the poorest class of possible contributor and suggesting that his gift should be his fair proportion of the present sum contributed by the public, we have no doubt suggested a possibility that we can never hope to see fulfilled. It is different when we turn to those more favourably situated and ask them to remember that upon them has fallen the task of keeping the average at its present pitch, and that upon them we rely for raising it to a still higher point. Among suggestions for helping the hospitals to attain a fixed income it has been said that to tax theatres and places of amusement for their benefit would be to levy a toll upon pleasure for the benefit of distress. That such a toll might well be levied upon many who rarely or never contribute anything to charity in the year we freely agree; but we would have it a voluntary one, levied by each man or woman upon himself or herself. Is the price that is paid without afterthought for the seat in the theatre pit or gallery too much for even the least well endowed to deny themselves occasionally, even if the denial involves the missing of a performance at the play? Is the price of the box or stalls anything that will seriously affect the comfort of him who pays it ungrudgingly perhaps several times during the run of a popular piece? Surely on one occasion he might bestow it to benefit his fellow-men. Pleasure is a costly item in the lives of Englishmen and Englishwomen, particularly in London, whether it is sought on golf links or racecourse, on polo ground or lawn tennis court, at the opera-house or on the river, or simply in the wearing of expensive costumes in public places or at private entertainments. If the tax, then, be self-inflicted let it be levied with an unsparing hand, remembering that those who will benefit by it ask for no pleasure, only for relief from pain. Let the giver of it, if he wants self-interest as well as charity for a motive, remember that the help he confers upon the hospitals may some day come back a hundred-fold upon himself. He may not belong to the class with which accidents are frequent in their daily work, but some day a mishap may lay him low so that the saving of his life may depend on the promptitude of succour. The doors of the nearest hospital will stand open for him as widely as they do for the labourer or for the poorest beggar in the streets. His life may depend upon the application of some new discovery of science, and let him remember that it is in the hospitals that such discoveries are brought to perfection. But while we suggest such possible selfish motives it is primarily to charity that we appeal.

As the Population increases the Fund should increase.

To the general hospitals last year the Fund distributed £28,175, to the special hospitals £15,559, and such sums, we are aware, mean important additions to the revenues of these institutions. We are anxious that the addition should be greater; that the part played by the Fund in the year's work of charity should be larger. Above all, we wish that its variations should be constant, and in one direction only, constituting a steady increase, as rapid as may be, from year to year. The year before last, all contributions told, the total was £40,397; last year it was £53,504. Are we justified in hoping that last year's figure may be maintained, or must we anticipate a drop back to something nearer the average of the past ten years? 1898 fell below that average; have we any reason to anticipate that 1900 will be better than 1898, with war in Africa and with famine and plague in India?

This is a terrible question for those who are actively engaged in the management of hospitals and who feel the anxiety, in all its keenness, without any power to evade it or remove its cause. They know the need of ample accommodation, of funds for repairs, of a larger staff perhaps, of freedom from debt, and of work unfettered by the necessity for daily parsimony. They watch the demand upon their space increasing as the population around them thickens, and they know that their income, which is inadequate even to maintain the existing state of things, instead of increasing, is stationary or actually diminishing from year to year. We can all see at a glance that the difference between the £28,175 given last year to the general hospitals of London and the £18,958 of 1898 amounted to over £9000, but only those who watch the incomes of individual institutions from year to year know how welcome the extra hundreds of pounds were to them; how important it is to the good work that their receipts this year should not be by so many hundreds less. The tables we give will suffice to show any who care to note it how the different amounts of the Fund in a bad year and a good year affect each hospital to which the Fund lends its aid, while those who have had experience in estimating the annual expenditure of large concerns will know how difficult it is to form such estimates with accuracy even under favourable conditions. And thoughtful persons will realise how hard it is to keep within a margin of safety when the income is insufficient and when such as it is it fluctuates to the extent of hundreds or even thousands of pounds.

Of the cases that demand treatment in our London hospitals we can show no statistics. The figures before our readers deal with those that have been actually treated in the past year, but do not show how many might have been treated had the accommodation and pecuniary resources of the hospitals been sufficient to supply their needs; no lists are made of those turned away from the hospital doors. The 65,461 in-patients taken in by the general hospitals constitute a greater number than those which we gave in our tables for 1896, 1897, and 1898, but if in this or any one year the number suddenly drops by four or five thousand it probably will not mean that there were less persons in London in need of aid; rather it will mean that owing to the condition of the hospitals' funds there were less beds ready to receive them. The increased number accommodated last year as in-patients may have distinct relation to the increased revenue of the hospitals through the larger amount of the Hospital Sunday Fund, and the splendid donations of the Prince of Wales's Hospital Fund. This is in the nature of speculation and conjecture. What is not either speculation or conjecture is that the population of this huge metropolis is from year to year growing larger. London grows greater, not because the members of its wealthier classes grow more numerous, although, no doubt, these to some extent increase in number. London grows greater because by the attraction of its wealth and by the promise of work which it is supposed to hold out to those without means of livelihood it draws from all parts of the country poor working-men with their wives and families; London grows greater because by the glamour of its opportunities and by the fame of the equal laws enjoyed by all in the British Isles it attracts from all parts of Europe many who are industrious and capable of useful work, many also who select it as a new home because where they come from they are oppressed. They are not oppressed in London, but it is to be feared that their destitution continues, and it may safely be said that of the thousands who yearly swell our population the greater number are of the class from which the inmates of

hospitals are drawn, while the overcrowding which their arrival causes does not tend to benefit the public health. Vast, therefore, as are the riches of London its poverty is vaster still, the poverty more than keeping pace with growth of wealth. In order to deal with this increase of poverty adequately there should be a correspondingly rapid, regular increase in the funds of our hospitals. And although the Hospital Sunday Fund enjoys what might be called good years at times, as the figures show, it cannot be said that even these years are good save in comparison with worse ones, and it cannot be said either that the improvement is rapid or regular.

In introducing our appeal to our readers in 1896 we pointed to the total of over £60,000 reached in 1895. We urged that the sum collected should not be allowed to recede again to its former lower level; but we were obliged to admit that having regard to the source of the sudden increase we feared that it might do so. In 1896 the total was lower than in 1895. In 1897 it was lower again, and again it fell a little in 1898. If in 1899 it rose once more, it was, as we have pointed out, owing to the magnitude of the "donations." And yet the Hospital Sunday Fund should appeal to all in a way in which the individual appeals of hospitals and other institutions cannot do, and for this reason. While asking all to give with the liberality that their means allow, we are aware that the subscription-list with its orthodox guinea is beyond the reach of many, while to many the publicity which it affords to their generosity offers no attractions. The bag and collection-box of the church, even the plate which gives a very modified publicity to the individual offering, should appeal to these in a way in which no more formal methods of subscribing can do. We are referring now to an enormous class, the class between rich and poor, the class with more or less fixed incomes, who are all competent to give something. It may not be a very great something, but it should be more per head than the twopence-farthing or twopence-halfpenny which represents, as we have shown, the average individual liberality of London towards the Fund. This is an age of education, in which men and women read and think and in which children are brought up to know and understand all that is going on around them. Not only by these pages and by such direct appeals as these, but by their knowledge of what is good and right, by their acquaintance with the facts of life and the many sides of the subjects that come before them, should the great mass of the population learn to support the hospitals as a duty imposed upon them by their humanity. We appeal primarily to Londoners, but those who live far from London should remember that London hospitals do not exist for Londoners only. Very few of those who are sufficiently interested in the welfare of their fellows to subscribe liberally to their local hospitals, and who might think this a reason for leaving the Metropolitan Hospital Sunday Fund unaided, but can remember persons who have been helped to be treated in London. Surely this is a reason why those who live in the country should support the Fund which aids all London hospitals. We may also point out to country dwellers that it is in the schools of the London hospitals that the majority of the medical men who carry on the work of the hospitals in the country, and who practise among the inhabitants of country districts all over England, have acquired their training.

In Memory of a Great Century.

Lastly, something of the nature of a centenary celebration might well be imported this year into the donations to the Hospital Sunday Fund. The last year of the nineteenth century is rapidly running out, and should not be suffered to close upon the Hospital Fund without a special mark from the public of their sense of what hospitals have wrought during the last hundred years. In no previous century that the world has known have the discoveries of science been so astounding, so calculated to amaze absolutely anyone who, having inhabited the globe during the century before, might be imagined as revisiting it during the later one. In no department of science has the revolution during the nineteenth century of all the conditions of our life been more marked than it has in medicine and surgery. It would be easy to multiply lists of surgical operations now possible that were not only undreamt of in 1800, but which, if conceived, could not have been performed with success. It is simpler to refer to the two great discoveries that have rendered others possible, and remind those who need to be reminded that antiseptic surgery and the use of anæsthetics are discoveries of the nineteenth century.

SUMMARY OF TABLES.

—	Hospital Sunday Fund award.	In-patients.	Relieved.	Cured.	Convalescent homes.	Remaining under treatment.	Died.	Out-patients' visits.	Accidents and emergencies

Dispensaries	2,102	—	—	—	—	—	—	963,223	—
Total	£50,386	121,893	39,883	62,306	10,948	7,759	8,277	4,262,778	307,068

Particularly appropriate is it to remind our readers of these at the present time, for during the raging war both these aids to surgery have produced a condition of things that without them would have been absolutely impossible. And preventive medicine is the child of this century. Again, let those who have friends in South Africa turn their minds thither and reflect on what our camps, filled with cases of enteric fever and dysentery, due to the conditions of warfare, the climate, and the country, would have become had not practical sanitation, combined with medical treatment, been brought to a high pitch of perfection by those responsible for the health of our troops. Let those who wish to compare the present with the not-far-distant past remember our military hospitals at Scutari, in which the death-rate is reckoned to have been between 400 and 500 per 1000, and reflect on the change wrought by modern organisation, sanitation, and surgery.

That the use of ether and chloroform, antiseptics, and x rays is not black art or witchcraft everyone in the present year of grace is fully aware, but even in the eighteenth century Professor Roentgen might have been seriously accused of *diablerie*. Perhaps all do not realise that such wonders as these are not due to the sudden inspiration of genius operating in the minds of specially constituted human beings, but are the results of patient investigation, anxious thought, and untiring research, carried on in institutions suited for the observation and investigation of the phenomena of injury and disease, while the mind that evolves the new thing as the result of observation and investigation is one that has received long and laborious training in those same institutions. There may be some, *laudatores temporis acti*, who at any rate profess to regret the introduction of railways, telegraphs, telephones, penny postage, or popular education, who, while perforce they admit that they constitute great changes, deny that they bring any change for the better into the life of mankind. No human heart, however, can view without thankfulness those changes in our conditions which tend to alleviate the human suffering which, while man exists, will be in some measure his lot. And such of these changes as have occurred during the nineteenth century are in a great measure due to the hospitals for which we plead to-day.

In Conclusion.

We have now given reasons why *all* should contribute to the Metropolitan Hospital Sunday Fund, laying special stress upon the word all, and including in it rich and poor, dwellers in London, in its suburbs, and in far-off country towns and districts without distinction. We make the appeal to those who attend public worship on the Sunday on which the collections are made, and we ask them not to let any who may not be present with them forget the Fund or omit to contribute to it owing to ignorance of its claims upon them. To those who attend no place of public worship the Fund should appeal as closely as to those that do, for the hospitals dispense their boons without regard to character, conduct, or religion, drawing no distinction between forms of belief or unbelief, holding that the claim of physical misery imposes a universal duty.

> In faith and hope the world will disagree,
> But all mankind's concern is charity.

And so we ask all to give to the full extent of their power of giving because—

1. The war and other circumstances of the year seem to endanger the prosperity of the Hospital Sunday Fund and of the individual hospitals.

2. Because the hospitals have done more than any institutions that anyone can name in mitigating the horrors of the war for those engaged in it; among whom names of dear ones will occur to individual givers, while all are their countrymen defending the honour and integrity of England and her Empire.

3. Because they are rich, whether their annual incomes are reckoned by thousands and hundreds of thousands, by hundreds or by tens of pounds, or by shillings paid weekly, compared with the poor for whom the hospitals are maintained and whose sufferings the hospitals struggle to alleviate.

4. Because they are in good health and it is the sick and the maimed who crave their aid.

5. Because they may some day themselves need the aid of the science which strives to perfect itself year by year by ceaseless work in our hospitals and constant effort to diminish pain and arrest the progress of disease.

6. Because for all men, for all women, for all children, rich or poor, sick or well, it is good to give, good to exercise self-denial in order to give, good to know that the gift is on behalf of those in worse estate than the giver, on behalf of those who do not crave aid themselves but for whose sakes we crave it.

Wherefore let our readers select any reason, selfish or unselfish, from the above that may please them, or frame a fresh one for themselves; but in any case let them give. And in giving themselves let them see that they do not omit to urge others to give also.

Audited and found correct, this 29th day of November, 1899.
(Signed) W. H. PANNELL & Co., *Chartered Accountants*, 13, Basinghall-street, E.C.

*** In the preparation of the voluminous statistics of hospital work which have been here digested and exhibited in collected form (and which have been specially supplied to us in response to our applications, and are quite independent of any returns made to the Metropolitan Hospital Sunday Fund Committee) we have been greatly indebted to a large number of secretaries and other officers of the various medical charities of the metropolis To them we desire, as on many previous occasions, to tender our sincere thanks.—ED. L.

Printed and Published by the REGISTERED PROPRIETORS of THE LANCET, at 423, Strand, W.C., and Nos. 1 and 2, Bedford-street, Strand, adjoining.

church or keeping a hospital going there is always the fear of the subscribers before the eyes of the responsible managers. In the building it is made a *sine quâ non* that it must be finished by such a date, while the decorations are handed over to a firm to complete at a fixed sum, instead of, as formerly, various artists being employed to carve or paint different portions at their ease. The modern hospital, too, has to issue reports; it is expected by the subscribers to show a good record not so much in quality as in quantity. Let an impartial observer look at the reports of any of the London unendowed hospitals and he will see what we mean. "Funds are urgently needed to meet the ever-increasing work; the patients come to us from all parts of the kingdom; the out-patient department is far too small to treat the crowds which daily flock to us for relief," and so on. It is easy to point out faults, but the suggesting of a remedy is by no means easy and we shall be glad to see at what conclusions the suggested conference will arrive. A central hospital board may succeed in Manchester but in London the subject bristles with difficulties.

CORTICAL HYPERÆSTHESIA IN ACUTE ALCOHOLISM.

A LENGTHY paper with accounts of cases illustrating the above condition has been published in the *Archives de Neurologie*, May, 1900, by P. Cololian and A. Rodiet of Magnan's Clinic. Cortical (cerebral) hyperæsthesia is manifested in its most marked form during the course of acute alcoholism. In such patients it is possible by external excitation to call up hallucinations in one or other of the sensory spheres, results due to the cortical hyperæsthesia which is present. Lipmann was one of the first to note this hyperæsthesia—e.g., as shown by the easy induction of visual hallucinations after pressure on the eyeballs. Krafft-Ebing has also shown that merely closing the eyes will suffice to make visual hallucinations come forth. Magnan has noted that taps on the skin can give rise to sensations of biting or of the sting of an insect and may also indirectly evoke hallucinations of sight, hearing, or smell in some subjects. Blowing into the external auditory meatus will give rise to auditory hallucinations.[1] Mierzejewski[2] observed that at the onset of delirium tremens there exists such an excitation of the visual centre that impressions of colour leave a long-persistent trace, and hallucinations occurring at such moments take the same colour. He observed in an alcoholic subject that tapping of the skin with a mallet provoked auditory hallucinations in the form of voices uttering insults. In one of his theses Cololian has recorded instances of persecutory delusions arising from simple hallucinations.[3] Stimulating the tongue with a piece of paper rolled to a point after closing the patient's eyes provoked intense illusions of taste, with grimaces of disgust. One patient said he tasted sulphate of soda or quinine and made a horrid grimace, another said it was absinthe, a third said it was sugar, while a fourth experienced merely an agreeable taste which he could not define. The diagnosis of such cortical hyperæsthesia is of great practical importance for it occurs before the actual onset of the symptoms of agitation, tremor, and acute cerebral excitement of delirium tremens, and it is possible by immediate treatment to prevent or to mitigate the threatened attack. Of the several cases recorded in the paper by Cololian and Rodiet the following may be taken as a typical and instructive one. A man, aged 32 years, a bath attendant, was admitted to the infirmary of the police depôt at Paris on June 13th, 1899. He had never been arrested before. His family history was as follows. His maternal grandfather was an alcoholic, his father was a sober man and was separated from his wife who drank wine and absinthe and who spent most of her money (which she had inherited) in drink and in dissipation. There were no children of the marriage except the patient. His personal history was as follows. He had had convulsions during his youth, and typhoid fever (lasting two months) at the age of 13 years. At the age of 18 years the patient drank to excess. His habitual drinking for 14 years thereafter was a small glass of "marc" on rising in the morning, white wine before breakfast, about a litre of red wine at each meal, and absinthe before dinner. After some time he had an accident and suffered from nervousness, and on medical advice he gave up taking absinthe to substitute for it almost immediately, however, a bitter liquor ("picon"). Soon after this symptoms of alcoholism appeared—viz., insomnia with nocturnal hallucinations, tremblings of the hands, and cramps of the calves. At the beginning of 1898 he was seized in the middle of the night with an attack of delirium tremens, and more recently, and before admission to the infirmary, he had a second attack. The patient had been married about a year. Before and during the first few days of his marriage he accused his wife of indifference, coolness, and deceit towards him with the connivance of her mother. For three months he appeared sad and depressed and spoke of shooting himself to put himself out of *ennui*. On admission to the infirmary he appeared red and flushed, with brilliant eyes and a face covered with sweat. There were tremors all over the body, the pupils were equal, and there was no speech disturbance. The pulse was rapid, and the respirations were normal. There was hyperæsthesia of the skin at the neck and on the chest, at the soles of the feet, and on the flexor surfaces of the fore-arms. "In all these hyperæsthetic areas the least rubbing produced agitation and contortions of the body with movements of defence, and the patient experienced actual pain." Tapping produced similar effects, whereas pinching had less effect. By Lipmann's method it was easy to provoke definite visual hallucinations of quivering flashes of light, sparks, and flames. Buzzings and roaring sounds were induced by simple suggestion or blowing on the ears. Touching the tongue with paper induced tastes of "powders and of absinthe" so strong and nauseous that he attempted to vomit. Smell was normal. The cortical hyperæsthesia with its hallucinatory tendency subsided and a gradually developing melancholia succeeded. He was transferred to an asylum, his bad hereditary antecedents making the prognosis unfavourable.

NON-COMPLIANCE WITH ISOLATION LAWS.

IN order to protect the members of the general community from contracting certain of the infectious diseases laws have been enacted which direct that all persons suffering from these diseases shall be isolated so as to prevent them from spreading the infection. When this cannot be done in private houses hospitals are provided by the authorities in which the necessary isolation can be carried out. As a rule there is but little difficulty in inducing the patients or their friends (in the case of those in charge of children) to conform to these laws, but occasionally ignorance or stupidity compel force to be used. An instance of this kind recently came before the Newmarket Petty Sessions. A man and his wife, who did not appear, were charged with wilfully exposing their daughter while she was suffering from scarlet fever. The evidence showed that the child was conveyed a distance of 10 miles in a cab hired at a posting establishment. On being told to keep her daughter carefully isolated the female defendant became very abusive. Subsequently the child was found in the public streets, and the mother being again

remonstrated with said she did not care about the law and should take or send her child just where she liked. It was also proved that the child had been sent to shops and allowed to play in the streets with other children, and another case of scarlet fever had already been reported. Mr. C. F. Gray, M.R.C.S. Eng., one of the magistrates, most rightly said that the case was a very serious one as the child would be for some time in an infectious state. A fine of £2 10*s.* with £1 8*s.* 6*d.* costs was imposed. Unfortunately, since the proceedings had been instituted the parents with the child had left the town, thus still further running the risk of spreading contagion. It is exceedingly difficult to teach such persons as the defendants in the above case that laws are made not for one but for the many. Isolation of persons suffering from infectious diseases is not designed for the sole benefit of the patients but for the protection of the public. The community must be guarded from the acts of such wilful persons in the same way as from those of criminals. It is a crime wilfully to allow a child suffering from scarlet fever to play with other children; many deaths may be the result, and the law consequently deals sternly with such offenders.

ENTERIC FEVER IN SOUTH AFRICA.

THE lists of casualties which appear daily in the papers demonstrate only too plainly that we have not yet solved the problem of protecting large bodies of troops from the ravages of such diseases as enteric fever and dysentery. Much has been done in prophylactic measures against the former but very much more remains to be done. One of the greatest difficulties which confront the medical officers is to induce the men only to drink water which has been rendered as pure as possible by boiling or filtering. After a long march the average soldier will run any risk to obtain a draught of water, however bad, and the consequences of such action were seen after the march to Bloemfontein when the men partook freely of the water of the Modder which was defiled by the dead bodies of men and beasts. One of the main interests attaching to the medical aspects of this campaign will be to ascertain the results of the inoculation against enteric fever which was practised upon many thousands of the officers and men. We have been informed that measures have been taken to ensure careful records being kept as to the occurrence of enteric fever amongst the inoculated and the uninoculated, but it will be some time before such statistics can be carefully formulated and the value of such inoculation estimated.

PNEUMOCOCCIC OSTEO-ARTHRITIS.

IT is curious that pneumococcic arthritis which is a recognised, though rare, affection in France appears never to have been observed in this country. At the meeting of the Société Médicale des Hôpitaux of Paris on May 18th M. Ch. Fernet and M. Lacapère read notes of a case recently under their observation. A strong man of alcoholic habits, aged 47 years, had an attack of pneumonia which commenced on Jan. 6th. The crisis occurred on the seventh or eighth day. He entered hospital on Jan. 13th. Soon after his admission traces of the pneumonia—bronchial breathing and sub-crepitant râles in the lower lobe of the left lung—were found. Two or three days before the patient was admitted arthritis of the right wrist appeared. It was characterised by swelling which was rather marked on the dorsal aspect and which was accompanied by slight redness and pain. On Jan. 24th exploratory puncture gave exit to several drops of a liquid as clear as water which was found on bacteriological examination to contain the pneumococcus. On Feb. 6th the patient had completely recovered from the pulmonary disease, but there were still engorgement of the wrist and slight œdema of the back of the hand. The wrist was then immobilised on a splint and slight pressure was applied by means of wadding. On Feb. 14th the swelling had diminished, but fluctuation was still evident and lateral movements of the wrist were accompanied by crackling. On March 2nd the swelling had further diminished and the pain had disappeared. On March 22nd the wrist was still swollen and the cellular tissue seemed to be infiltrated. The axis of the hand was deflected outwards as if the radius was eroded at its extremity and the joint crackled on passive movement. Radiography showed on the sound side the bones of the forearm and the carpus clearly separated; on the diseased side the wrist was represented by a greyish mass, the ends of the bones of the forearm seemed to be in contact with the carpus, and the extremity of the radius was eroded and enlarged. There were thus evidently adhesions between the radius and ulna and the carpus. The case was one of pneumococcic periarthritis similar to two cases already reported to the society.[1] The lesions shown by the radiograph corresponded to those previously observed at a necropsy in another case of the disease. A similar rapid course, early erosion of the bones, and formation of adhesions have been observed in all cases. Ankylosis seems to be the natural termination. Pneumococcic osteo-arthritis is thus a special type of arthritis which is clearly distinct from pneumococcic synovitis.

COUNTY OF DURHAM SOCIETY FOR THE PREVENTION AND CURE OF CONSUMPTION.

THE above society has just opened its new sanatorium. The building is Horne Hall, at Stanhope, which stands in two and a half acres of garden, and the first instalment of patients entered on May 15th. At present there is only accommodation for 12 patients, but in the course of the summer it is intended to increase the number of beds to 20 by adding more bedrooms. The sanatorium will be maintained—(1) by ordinary subscriptions which may be allotted for the benefit of patients from particular districts or works; (2) by workmen's subscriptions, each man paying 3*d.* per quarter, and bodies of workmen subscribing regularly shall have a first claim on the beds to the full amount of their total subscriptions—e.g., if the total sum of their subscriptions amounts to half the cost of maintainence, half of the beds will be at their disposal without further payment; (3) by weekly payments by or on behalf of patients who do not belong to bodies of regularly subscribing workmen; and (4) by income from investments. There is to be a resident medical officer, who must be registered according to the Medical Acts, who shall devote all his time to the welfare of the inmates of the sanatorium and shall have his meals with them. He may have 21 days' holiday in the course of the year at times to be approved by the committee, and nothing is said about his getting any salary, although we suppose he is to have one.

URTICARIA HÆMORRHAGICA.

IN the *Intercolonial Journal of Australasia* of April 20th Mr. C. S. Hawkes has published a case which is of interest both on account of the rarity of the condition present—hæmorrhagic urticaria—and the medico-legal question which might have arisen. A boy, aged 21 months, was let fall by his nurse. He was supposed to have struck the back of his head, but the accident appeared to have been a slight one and no notice was taken of it at the time. Next morning there was a somewhat tense swelling about two inches in diameter on the right side of the back of the neck, reaching up to the level of the occiput, with dark bluish discolouration in the centre as from a bruise. There were also two bluish marks "like bruises"

[1] See THE LANCET, Dec. 11th, 1897, p. 1548.

over the left lower ribs. In the afternoon the cervical swelling was tense and painful, and over the body were many typical urticarial wheals varying in size from a quarter of an inch to two inches in diameter. All the larger ones showed deep purplish discolouration, and there were some bluish marks on the skin, evidently where wheals had disappeared. Itching was considerable. On the first day the wheals were confined to the trunk; on the second day they spread down the arms and hands; on the third day they were thickly distributed over the trunk, legs, arms, and face, and the eyelids were so swollen that they could not be opened. The hæmorrhages were chiefly confined to the larger wheals, which appeared in successive crops. In 24 hours they began to turn from a dark bluish purple to a brown colour. They had disappeared by the fourth or fifth day. After the fifth day only ordinary wheals appeared. Two days later a most severe attack of ordinary urticaria occurred. At its height there were attacks of dyspnœa with sonorous and cooing rhonchi, which passed off in from a quarter to half an hour. For a few days the cry was very hoarse and there was evidently sufficient laryngeal swelling to cause some inspiratory retraction of the chest. As the urticaria disappeared bronchopneumonia supervened, which was followed by whooping-cough. During the hæmorrhagic period examination of the blood showed decided leucocytosis. It is to be regretted that further details are not given of this highly interesting case. Mr. Hawkes appears to consider that the injury had no relation to the eruption for he does not even discuss the question. However, the large cervical swelling seems probably to have been due to the fall, especially as it differed so much from the other cutaneous hæmorrhages. The facts may be regarded as evidence of the hæmorrhagic tendencies of the patient.

THE CATARRH PRODUCED BY A 2 PER CENT SOLUTION OF SILVER NITRATE IN THE EYES OF NEWLY-BORN CHILDREN.

IT must have happened to many practitioners who follow Credé's teaching and introduce one or two drops of a 2 per cent. solution of silver nitrate into the eyes of newly-born children to find that the application sets up a good deal of catarrhal conjunctivitis. The question as to whether the occurrence of such an inflammatory reaction is the usual result of the treatment or not has aroused a considerable amount of controversy. Professor Leopold attributes the catarrh to a faulty technique; other authorities hold that it is the usual sequel and consider it a serious drawback to the treatment. With a view to settling the question Dr. H. Cramer[1] has investigated the effect of a 2 per cent. solution of silver nitrate upon the eyes of 300 newly-born children. One drop of the solution is placed in each eye while the child is lying upon the back. The baby is then rolled over on to either side alternately and by the successive opening and shutting of the lids the lotion is spread all over the conjunctival sac. The eyelids and the surrounding parts are then carefully wiped dry with cottonwool. In all the cases the conjunctiva was found to react to a greater or less degree, varying from simple congestion and swelling to an acute inflammation. In 5 cases only out of 100 which were carefully observed was there no discharge, the effect being limited to some redness and swelling of the mucous membrane. In the remaining 95 cases there was an abundant discharge. In 73 cases it lasted about five days while in 27 it continued for a longer period of time. In 11 cases a secondary infection occurred with a recrudescence of the symptoms. Dr. Cramer is inclined to believe that the reaction is more marked in children who have been born after a difficult labour or who have presented by the face. In two cases of ectropion of the upper lid the inflammation was extremely marked. The length of time the discharge lasts appears to depend upon the presence or absence of organisms in the conjunctival sac. For the first 24 hours the discharge is aseptic, but after the second day it contains numerous organisms of various kinds. In all the cases of secondary infection staphylococci or streptococci were found to be present. These investigations tend to confirm the view that the use of a 2 per cent. solution of silver nitrate is normally followed by a certain degree of conjunctivitis which tends to spontaneous cure and gives rise to no bad results. The fact that such a reaction does occur is no doubt the explanation of the unpopularity of this mode of treating the eyes of newly-born children with some medical men and with a great many monthly nurses. The dangers of ophthalmia neonatorum are, however, so great that there is no justification for neglecting any precautions that may tend to prevent the occurrence of this dread disease. There can be no doubt that the use of a 2 per cent. solution of silver nitrate is one of the most certain means of prevention, and its more general use would be of the greatest value in tending to diminish the very large number of cases of ophthalmia neonatorum which at the present time occur in midwifery practice.

THE ALLEGED POISONOUS COPPER-COATED MAUSER BULLETS.

IT has been stated pretty freely in the daily press that amongst other unfair devices adopted by the Boers in the present war was that of coating the Mauser bullet with a poisonous salt of copper — viz., verdigris. Strictly speaking, verdigris is basic acetate of copper, which may be obtained by allowing vinegar to come into contact with, or to evaporate on, a used copper coin. The same French word, however, has been applied, but wrongly, to the green rust (basic carbonate of copper) which forms on copper when in contact with moist air. Our Special Correspondent at the base also stated in a letter published in THE LANCET of May 5th, 1900, p. 1312, that he had seen a "clip" of Mauser cartridges the bullets of which had been dipped in verdigris, but in our issue this week he reports that on being submitted to a thorough analysis this green coating proved to be not verdigris but a mixture of paraffin wax and carbonate of copper, which, he adds, appears to have been used for the double purpose of preventing the cartridge suffering from damp and of supplying a hermetical closing between the brass capsule and the bullet, and thus preventing rust of the barrel. By the courtesy of Sir William Mac Cormac, who placed at our disposal some of these so-called copper-dipped bullets, we have been able to submit the coating as well as the nickel case which encloses the lead bullet to complete analysis. The results are of special interest in regard to the accusations made as to the sinister intentions of our enemy, and we are confident that the interpretation to which these results lead is correct and absolves absolutely the Boers from the charge of tipping the Mauser bullet with a poisonous salt. It is essential to state that the Mauser cartridge consists of a brass case (containing the explosive and detonator or cap) to the anterior end of which is attached a bullet of lead inclosed in a nickel jacket. The Mauser bullets which we examined were covered seemingly with a green coating extending from the apex of the bullet to about a quarter of an inch along the brass cartridge case. On scraping this wax carefully off, however, the first shavings proved to be quite colourless and, in fact, consisted of paraffin wax such as is used in making modern candles. As the scraping approached the surface of the nickel case the shavings became light green until on the surface itself the scrapings were quite green. The nickel

case proved to contain on analysis not only nickel but copper, and the green wax contained both those metals also. We have not the slightest doubt, therefore, that the bullets in the first instance were steeped in melted paraffin wax or wax candles solely to prevent fouling of the gun-barrel and to protect the nickel case against rusting, to which this metal is particularly liable, and that after a time both the copper and nickel of the case of the bullet entered into combination with the stearic acid (which is commonly added to wax candles) in the wax and turned it green. The same phenomenon is familiar to everybody in the green tears of a wax candle in a brass candlestick. It has been suggested that the colouring was of arsenical origin, but we failed to find the slightest trace of arsenic. The fact that the wax on the bullets contained precisely the same metals as were present in the case entirely sweeps away the suspicion that the Boers entertained a malicious intention and expressly coated their Mauser bullets with poisonous copper salts. This should be stated with some emphasis in order that our enemy may be treated with common fairness. Further, it is doubtful whether the bullet would carry the smallest amount of this green wax coating (considering its comparatively low melting point) to its billet. The metals only existed in traces. Many erroneous and contradictory statements have been made in regard to this matter and we are glad to be able to present such a satisfactory and, as we believe, perfectly true interpretation of the facts as revealed by analysis, which hitherto does not appear to have been carried out at that length or with that precision which the serious nature of the suspicion demanded.

THE HUXLEY LECTURE.

AS will be seen by a reference to our advertisement columns Lord Lister has consented to deliver the third Huxley Lecture at Charing Cross Hospital on October 2nd. The lectureship was founded upon the death of Professor Huxley out of a sum raised by the medical school of Charing Cross Hospital and various friends in commemoration of Huxley having received his medical education at Charing Cross Hospital, and the subject appointed was that of Recent Advances in Science and their Bearing upon Medicine and Surgery. The first lecture was delivered by Professor Michael Foster in 1896 and the second in 1898, the lecture being biennial, by Professor Virchow. Lord Lister is a worthy follower of his two distinguished predecessors and his selection as lecturer in the present year is all the more fitting on account of our country being at war. The extraordinary and unprecedented success which the Royal Army Medical Corps has attained in the treatment of the wounded is due in very large measure to Lord Lister's world-renowned researches upon asepticism and its results.

THE Helen Prideaux Memorial Scholarship, value £50, will be awarded in July, 1900, to a graduate of the London (Royal Free Hospital) School of Medicine for Women. Candidates must be registered medical women of not more than three years' standing on June 1st, 1900, and must send in to the trustees, under cover to the secretary, an essay on some medical subject, on or before July 15th, 1900. The subject chosen by each candidate may be connected with any department of medical or surgical practice. In estimating the relative value of the essays the trustees will attach special value to the evidence afforded of clinical work and of direct and personal experience.

AT a general monthly meeting of the members of the Royal Institution held on Monday, June 11th, Sir James Crichton Browne, treasurer and vice-president, being in the chair, the following motion was unanimously agreed to:—

The managers of the Royal Institution of Great Britain, on the occasion of the retirement of Sir Frederick Bramwell from the office of honorary secretary, desire to place on permanent record an expression of their high appreciation of the admirable way in which he has performed the duties of that office and of his signal services to the institution generally.

THE Ingleby Lectures of the Mason University College, Birmingham, will be delivered on Wednesday, June 27th and July 4th, at four P.M., in the medical lecture theatre of the College, by Dr. O. J. Kauffmann, who has taken for his subject "The Commoner Neuroses of Childhood, their Pathology and Treatment."

Staff Surgeon Henry Peacock (retired R.N.) died on June 5th in his eighty-eighth year. He qualified in 1837 and in 1839 entered the Royal Navy. Subsequently he was appointed medical officer to the Dockyard at Chatham and staff surgeon to the Royal Dockyard Battalion.

A REUTER'S telegram states that Dr. J. Farrell Easmon of Cape Coast, West Africa, died from pneumonia on June 9th.

THE WAR IN SOUTH AFRICA.

THE war chronicle for the past week is of a mixed but, on the whole, of a very satisfactory character. It is nevertheless disappointing to learn at this stage of the campaign, and despite all the experience which our army has had of the tactics of the enemy that we still appear to be unable to prevent isolated bodies of troops and detachments from being surprised, surrounded, and defeated by superior numbers of the enemy. The defeat and capture of the Sherwood Foresters' (4th Derbyshires) Militia at Roodeval was a regrettable business, notwithstanding that it can have no real influence on the course of the campaign. The direct result of the wrecking of some miles of railway by the Boers and the consequent interruption of Lord Roberts's line of communication cutting him off from his base at Cape Town put a temporary check on his military operations. These occurrences indicate that the spirit and activity of the Transvaalers and Free Staters are factors which have still to be taken into account. Nevertheless, with the occupation of the enemy's capitals, with the successes we have obtained in capturing Botha's Pass and Almond's Nek by Buller's troops, and the news from the Western side and elsewhere, taken in connexion with the overwhelming forces at our disposal, we may confidently assert that the enemy's back is broken. The Boer forces may strike a furtive blow here and there, successfully attack different points and intercept Lord Roberts's long lines of communication from time to time, and by making occasional raids and then skilfully retreating cause the war to drag on, but these efforts must inevitably only prove futile in the end. How soon that end may now come no one can tell, for just at the moment of our writing the welcome telegraphic news has arrived of Lord Roberts's successful attack on Botha's force, and of the defeat and complete rout of De Wet by Lord Methuen's troops. The most unsatisfactory part of the business has hitherto been the way in which the Boers have usually succeeded in retreating without loss of their guns and convoys or any material loss to themselves. The British have rarely succeeded in "cornering" them so as to compel their surrender. We hope that it is true what a telegram from Pretoria, dated June 5th, says—namely, that 150 officers and 3500 men whom the Boers held as prisoners had been released. The Boers had intended to take all the British prisoners with them on evacuating Pretoria, but were frustrated by the arrival of the British invading force. Mr. Krüger nevertheless succeeded in taking away about 900 with him as hostages in his retreat towards the East. The casualties in the Sherwood Foresters' Militia at Roodeval were 36 killed and 104 wounded, and the news of the disaster

appears to have been telegraphed by Major Stonham, the medical officer commanding the Imperial Yeomanry Hospital. Lady Georgiana Curzon, president of the Imperial Yeomanry Hospital Committee, has since received the following cable from the Military Secretary, Cape Town: "Imperial Yeomanry Field Hospital in action, Roodeval. All safe."

Large batches of sick and wounded are arriving in this country by different transports. The steamship *America* (Transport 79) reached the Albert Docks last Saturday and disembarked 14 officers and 310 men invalided from South Africa. The ship left Cape Town on May 12th and had a good voyage, only two deaths occurring on the way. The whole of the men, of whom about 50 suffered from the effects of wounds, benefited greatly in health. 80 lying-down cases were on board at the beginning of the voyage, but with six exceptions these were convalescent on arrival. Three men very ill with enteric fever were transferred to Denton Sanitary Hospital and there were three cases of a serious nature for the Herbert Hospital, Woolwich. Dr. C. F. K. Murray and Dr. L. H. Hitchens were in medical charge, having the assistance of three nurses.

The transport *Orotava* arrived on June 10th with about 600 sick and wounded soldiers from the front, nearly all convalescent, there being only some 12 bad cases on board on arrival. Most of the men were transferred to Netley and the remainder to Colchester. Other transports are on their way home and arrivals will, of course, be of frequent occurrence. Meanwhile, strong reinforcements are leaving this country for the front. The home barracks are crowded and recruiting is going on apace. The saying is no doubt true enough that if we are not a military, we are nevertheless a warlike, people.

The last return issued by the War Office showing the total casualties since the beginning of the war up to the end of last week gives the total (exclusive of sick and wounded now in British hospitals in South Africa) as 25,728. The list is made up as follows:—

—	Officers.	Non-commissioned officers and men.
Killed in action	235	2,283
Died from wounds	63	551
Missing and prisoners (excluding those who have been recovered or released)	186	4,486
Died from disease	112	3,609
Accidental deaths	—	58
Sent home as invalids	664	13,481
Total	1260	24,468

The returns received by the last mail from the Portland Hospital in South Africa show: total admissions in hospital, 762; returned to duty, 108; sent to England, 98; convalescent, 258; deaths, 14; transferred to other hospitals at base, 133; remaining in hospital, 151, including 91 cases of enteric fever. In consequence of the fever epidemic 60 additional beds have been opened, making 160 in all, and two of the nursing sisters from New Zealand had been added by the War Office authorities to the hospital. The amount of sickness in the neighbourhood of Bloemfontein is abnormal. Further additional stores sent from England were being received at the date of this communication—viz., May 18th.

In consequence of the prevalence of the fever epidemic the Imperial Yeomanry Hospital has been compelled to provide a considerable number of additional beds, and large stores of hospital clothing, linen, &c., are being received. This reminds us that considering the enormous pressure on the lines of railway at the Cape there is much difficulty and delay in forwarding and distributing the stores sent out from this country. It would be well, then, for people forwarding gifts in kind to the hospitals and troops to try to find out beforehand whether supplies are procurable or not at the particular towns and stations to which they intend to despatch them, and, if they are, to forward cheques and money orders for their purchase locally. The diurnal variations of temperature in South Africa are already great and very trying. The nights are very cold and the troops—especially the sick and wounded—will need ample supplies of warm underclothing.

At the present time the sick in our hospitals altogether outnumber the wounded. The principal diseases are enteric fever and dysentery and sufferers from these complaints are sincerely to be pitied; they will stand in need of all that can be done for them in the way of good nursing and the most careful dieting. From what we have heard we may say that those who happen to know any of the nurses serving at the front and the particular hospitals to which they are attached would find it a good plan to send periodically any articles of clothing by parcels' post to their address for the use at discretion of the patients under their care. Supplies of this kind are often useful to meet emergencies or to provide for sick and wounded when leaving the hospital.

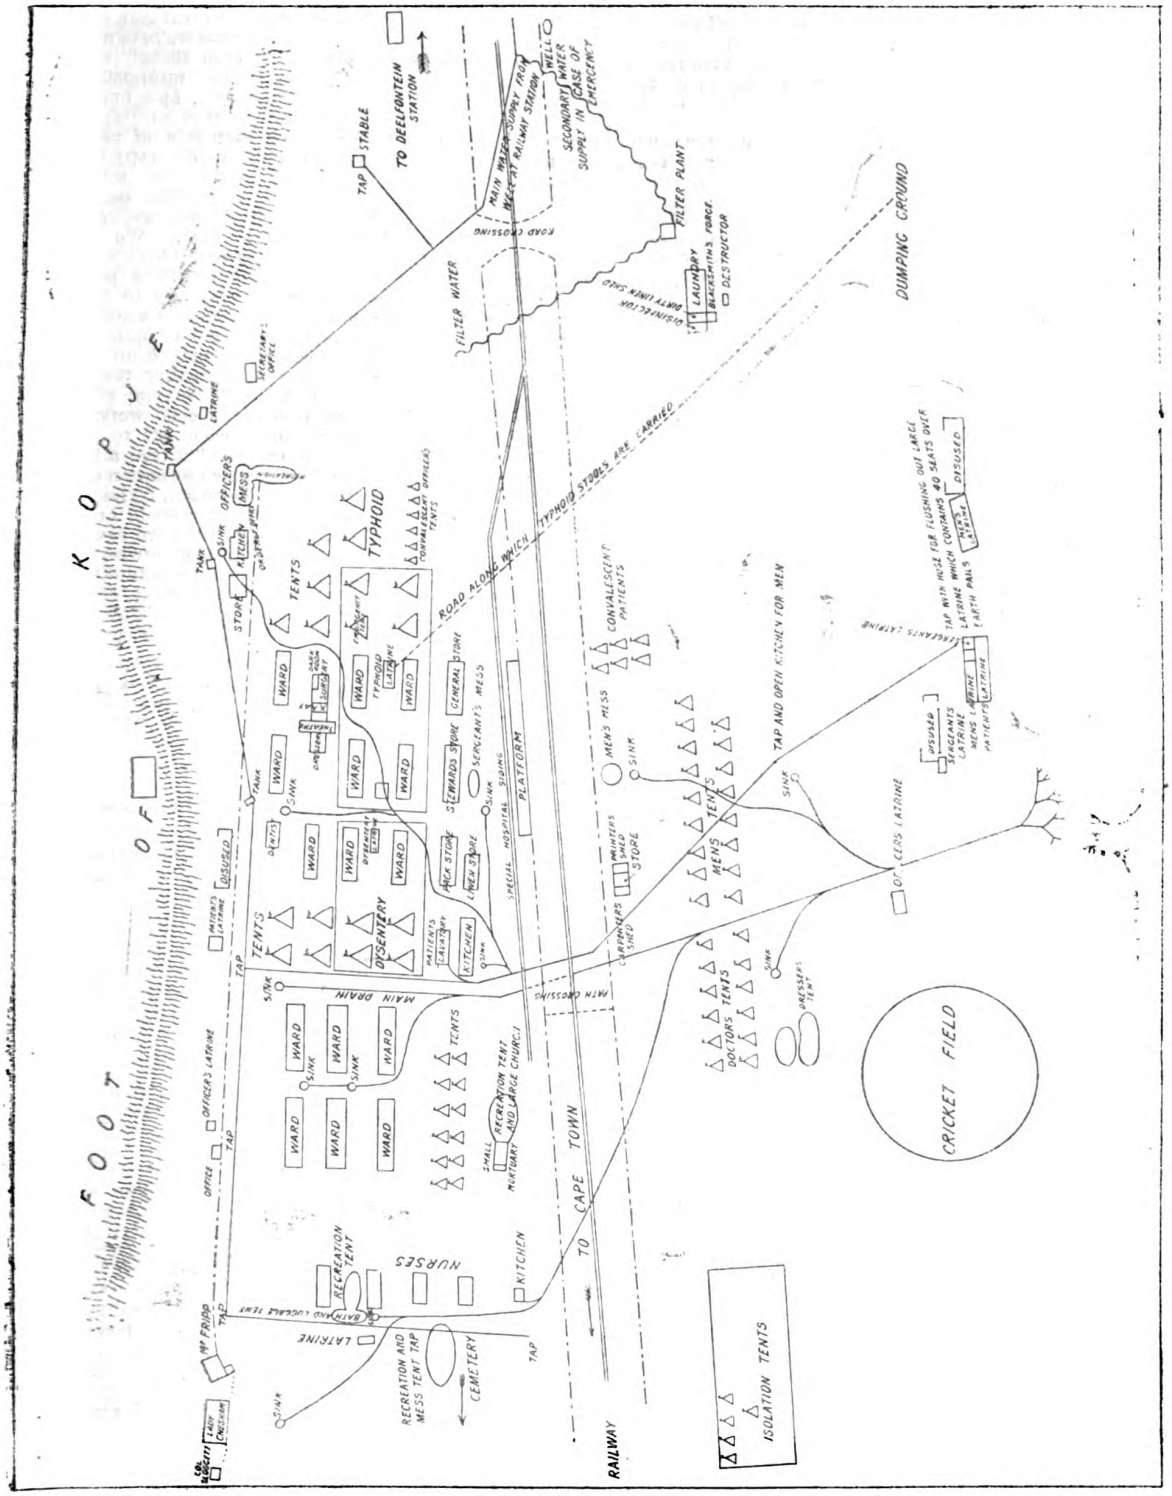
THE IMPERIAL YEOMANRY HOSPITAL.

BY ALFRED D. FRIPP, M.S., F.R.C.S.

Though there are still two of the English huts unfinished the Imperial Yeomanry Hospital has in all other respects reached at last its full state of development and I thought you might like to have a short account of some of the main features. The appended plan of the hospital grounds has been prepared by Dr. Barclay Black and with that plan in front of me I have jotted down a description of its various parts as one meets them in taking any visitor for a tour of inspection. Dr. Black, who is my staff officer, superintends all the work of the cleanliness and latrine departments of the camp. His plan not being the work of a skilled surveyor does not pretend to be of more than approximate accuracy as to distance, but it is at least faithful in intention and in effect.

To take first the smaller half of the hospital, which lies to the right of the railway line as you arrive from Cape Town, we have a group of isolation tents, for, like other base hospitals, we have not been exempt from the occurrence of an occasional case of scarlet fever. Further to the right are the tents of the medical staff, the two marquees being occupied by the ten surgeons' dressers. The bell tents occupied by the detachment of about 100 orderlies are seen to be separated by the main drain and also by the main road which leads from the wards to the main latrine from the tents of the medical officers. The main drain is made of four-inch earthenware pipes and is fed by various sinks throughout the hospital grounds. No solid matter is allowed to be thrown into the sinks, nor any infected water from the enteric fever department (this is all carried by our natives along the route indicated not far from the laundry to the dumping ground), nor greasy water from the kitchens (this is used to feed the pigs), nor does the drain go near any latrine or any water-supply pipe. Practically the only thing thrown down the sinks is water that has been used for washing. The main drain discharges by means of a system of subdividing trenches on to a part of the veldt which has a good incline away from the hospital. Between the bell tents and the railway line is placed a galvanised iron building which is subdivided into a central dry canteen for the orderlies and two lateral compartments forming workshops for the carpenters and painters respectively. Then comes a large tent used by the orderlies as a mess-room, recreation-room, and bath-room, followed by a collection of hospital marquees which are used only when the hospital is over full for the temporary accommodation of convalescent patients awaiting a train for transfer to Cape Town. The main urinal and latrine are shown towards the bottom centre of the plan. It has separate compartments for the sergeants, the orderlies, and the hospital patients, and we consider it a masterpiece for the Karroo. The floor is cemented throughout and for four feet outside the corrugated iron walls it is inclined and grooved so efficiently that the four natives, who are always on duty there, can, when they are not busy carrying buckets away to the dumping ground, frequently flush out the whole enclosure by means of an armoured hose which has a good head of water from a standpipe. The washings are collected in a cement-lined pit just outside and are thence removed in buckets to the dumping ground. No buckets come back from the dumping ground to any part of the hospital without having undergone a prolonged soaking and subsequent thorough cleansing in a large tank of disinfectant at the dumping ground. The bedpans and the urine-receivers from all patients in the hospital who are not able to walk to this latrine are carried thither by the orderlies and left in a special annexe, clean utensils being taken back to the wards in their place. The excreta are removed to the dumping ground by the natives at 6 A.M. For the enteric fever

and dysentery departments special disinfecting latrines are provided, as will be described later. To the right, in and near the laundry are (*a*) a Washington-Lyons disinfector capable of dealing with nine mattresses and many smaller articles in each batch; (*b*) a Russian bath for the treatment of stiff limbs which are so frequent both from rheumatism and from injury; (*c*) a blacksmith's forge; (*d*) a refuse-destructor, through which all paper, straw, small boxes, empty canned-meat tins, and other camp litter are passed, and the ash is then buried; and (*e*) a large filter plant by Messrs. Defries, which is driven by steam from the laundry and is large enough to cope easily with all the drinking water of the hospital. The laundry plant is large and efficient. It has been supplied by Messrs. Defries and is worked by men sent out by that firm, who are helped by four of the wardmaids and some 15 natives. It easily deals with the washing of the 700 white individuals at present in our camp. All of this plant is housed in corrugated iron sheds. All mattresses, bedding, and linen from the enteric fever and other infected wards are put through the Washington-Lyons disinfector at 7 A.M., having been stored, if necessary, overnight in an annexe of the enteric fever latrine between the huts occupied by enteric fever patients. The last point to note is the secondary well which has been sunk on the way to the station as a resource in case of emergency, but we have not yet had to fall back upon this water-supply, as that from the railway well at the station has proved amply sufficient for our needs.



If we now retrace our steps to the main drain and walk up a slight natural incline to the railway line and cross the latter at the most southerly of the three level crossings indicated in the plan, and, starting from the extreme south of the hospital grounds, walk northward among the wards, we shall be going up a slight hill nearly all the way. The cemetery, a quarter of a mile off towards Cape Town, lies at our back. On our left-hand side is a group of three private residences and the sisters' quarters, which consist of: (*a*) four huts, the upper two of which, which are the largest, are occupied by the 29 day sisters, the next one by the 10 night sisters, and the fourth by the 10 wardmaids and the housekeeper (Miss Cheesman), whose services have been of the utmost value, for she not only attends to all the domestic arrangements of this department, but also superintends the laundry, which in itself is a very onerous and important task in view of our isolated position from the rest of civilisation; (*b*) the kitchen, which is seen close to the railway; (*c*) the luggage tent, which is placed between the two upper huts and opens into (*d*) the bath tent, which has its own supply of cold water from the main and of hot water from a boiler placed half way between the three private residences and the sisters' quarters, as well as its own sink just outside the tent for discharge into the main drain, the interior of the tent being separated by curtains into several bath rooms and the floor boarded; and (*e*) the latrine just behind the bath tent, which, like all the other latrines in the hospital, is worked on the bucket-and-earth system and served by natives who withdraw the buckets by means of a trap-door at the back of the seats without going into the latrine. The group of six large huts, sent out from England by Messrs. Boulton and Paul of Norwich, with a foreman to put them up, are a great success. They are admirably suited to the climate which yields considerable extremes of temperature in 24 hours and they are well ventilated. The material employed is corrugated iron outside, wood inside, and felt between. Each will be provided with a verandah as soon as the carpenters have time to get to work on the many similar improvements required throughout the hospital. Hitherto they have all been busy with the absolute essentials of construction. Each hut accommodates 34 patients without any crowding. The middle one of the first row that we come to is full of officers and the one just above it is full of Yeomanry. Sinks are shown contiguous to all the huts throughout the hospital, and the water-supply is drawn by the orderlies in cans from stand-pipes placed at convenient distances outside the hut. Boiler tanks are also scattered about the hospital so that there is an ample supply of both hot and cold water. Each hut has a lean-to outside for washing-up purposes. Below these on the plan will be seen a group of a dozen tents, half "tortoise" tent and green in colour and half "hospital" marquee. Each tent is equipped to accommodate eight iron frame and spring mattress bedsteads permanently, with which luxuries the hospital is provided throughout by the Birmingham Bedstead Manufacturers, but each tent is in addition liable to have thrust upon it in times of emergency four or five trestle beds. Close to these tents is the patients' large recreation tent, which on Sundays is transformed into the body of a church. The chancel, which is sufficient for the needs of the week-day services, is formed by a small hut separated from the recreation tent by large folding-doors and from the mortuary at the altar end by a thick partition. The mortuary, like the latrines, has a cement floor and a table and galvanised iron walls. No dead body lies there for more than 24 hours. Five o'clock is the hour for funerals. These, of course, are military, though the salute is dispensed with for fear it should disturb those patients who are in a precarious condition.

Thanks to the kindness of friends at home there is a most excellent library and supply of periodicals. These are in great demand. The books are kept in cases in the recreation tent, and Mr. Atkins, one of the surgeons' dressers, performs the duties of librarian. Similarly Mr. William Turner, one of the surgeons, presides over the distribution of all the indoor games throughout the hospital and organises all the outdoor sports, including cricket, football, lawn tennis, golf, &c. All the requisites for these games have to be procured in Cape Town and they are very expensive. The ground, also, does not lend itself at all favourably to the necessary preparation of level areas, so that we have had great difficulties to overcome. Then there is a group of eight white "tortoise" tents, larger than the last, for they accommodate ten permanent bedsteads, and beside them will be seen patients' lavatory and bath hut; it has a cement floor sloping to a sink in the corner and a good water-supply. In the kitchen hut all hospital food is cooked and the cooks have stores and offices. A latrine is placed between the two acute dysentery wards, On the plan a line is seen drawn round the dysentery department; this indicates that four of the "tortoise" tents mentioned already are included. These four are used for the convalescent dysentery patients.

Above the dysentery department is shown another hut, and above that again the small hut used by Mr. Newland-Pedley as his store-room, work-room, and living-room, though the actual operative dental work is carried on in the second or spare operating theatre to be described later. Below the dysentery department are seen the huts that house the pack store and the linen store. Close together are the sergeants' mess tent; a group of five convalescent tents; small tents, each house a convalescent officer; the officers' mess, into which opens the officers' recreation room, the secretary's office, a small latrine, the orderly's room, the store and kitchen for the officers' mess, and the dairy, from which the milk for the entire camp is dispensed after sterilisation by several large Aymard sterilisers. Miss Brereton, in addition to her work in the operative surgical department, presides over the work of the dairy. Half way to the station are the stable and coach-house in which a couple of Cape carts, each drawn by two horses, a cart which carries the linen backwards and forwards to the laundry, and the riding horses of the various officers, both medical and combatant, are housed.

This leaves for description only the enteric fever department and the cross-shaped surgical building.

In the cross-shaped building shown in the upper third of the plan towards the centre are the operating theatres, the surgery and dispensary, the x-ray department, and the surgical store. The last-named forms the head of the cross and, with the two operating theatres, is in the charge of Miss Brereton, till lately the sister in charge of the pay wards at Guy's Hospital. In her surgical store are accumulated all the supplies of instruments, dressings, antiseptics, anæsthetics, splints, trusses, and other medical and surgical paraphernalia. It is separated by a roofed-in open-air lobby from the operating theatres, one of which is devoted, except in times of stress, to the dental surgeon. The two theatres form the cross-piece of the cross. The theatre used for surgical operations is admirably equipped and furnished, Messrs. Down Brothers, who executed the order for all the instruments, having presented a complete set of aseptic metal furniture, including washhand stands, stools, dressing-tables, and a raise-and-lower table. The wooden lining of the theatre has been painted white. There are two large slabs of corrugated glass which give an excellent top light. The wooden floor is covered with linoleum. The doors are four

Plan of the Imperial Yeomanry Hospital. Prepared by Dr. Barclay Black.

feet wide, giving easy access for the bearers from the open air or from the x-ray department. The long limb of the cross is also separated from the operating theatre by a roofed-in air-space and is occupied as to the end nearest the operating theatre by the x-ray department (which is singularly well equipped and is doing most excellent work under Mr. Hall Edwards), and as to the foot of the cross by the surgery and dispensary. The photographic dark-room is placed in the furthermost corner of the dispensary, so that the large store of plates shall not be spoiled by the proximity of the x-ray apparatus.

The enteric fever department consists of four huts which accommodate from 22 to 26 patients each. In the centre of the department is a corrugated iron hut, half of which is used as a disinfecting latrine for the infected excreta and the other half for the storing of used linen and bedding, including mattresses, until the regular hours which are appointed for the transference of these infected articles to the Washington-Lyons disinfector. All the bed-pans and urine utensils used in the department, and also all the water with which the patients have been washed, are carried by the orderlies to this enteric fever latrine and are there emptied into large pails containing izal and disposed on the concrete floor, while on the zinc shelf there are sets of zinc baths (labeled A and B) for the thorough disinfection of all the utensils. In the baths marked A the utensils are swabbed out with izal solution and they are then put to soak in a similar solution in baths marked B until required again in the wards. An intelligent native is always on duty at the typhoid fever latrine swabbing out the walls and floor and iron shelves, which are all sloped especially to facilitate this process, while two other natives are continually on duty carrying the pails of the disinfected excreta away by the route indicated on the plan to a special dumping ground in a natural hollow far removed from the camp. The pails brought back from the dumping ground are fished out from a large tank of carbolic and the dirty ones are put in their place to undergo a similar soaking before they go back to the latrine.

The staff of attendants on duty in the typhoid fever department is entirely separate from the rest of the sisters and orderlies. Thus one of the senior sisters is in charge of the nursing staff which consists of a day sister and a night sister for each hut and a day sister for every two tents and a night sister for every three tents. Similarly a special ward-master is in charge of the orderlies, of whom there are two on duty with each day sister and one on duty with each night sister. The day staff and the night staff are each on duty for 12 hours in this department, their occasional holidays being arranged for by there being always one extra sister and two extra orderlies in addition to those already mentioned. By this means not only is efficiency ensured among the attendants of the department but also uniformity in the methods adopted for carrying out the rules. These rules have been printed and given to every attendant and are strictly enforced. There is a special hut between the two left-hand wards for the use of all sisters engaged in the department and here they have their tea, &c., for the taking of any food by the attendants or even the preparation of food in the wards is, of course, strictly forbidden. There is also a special lavatory for the enteric fever attendants, so that they may be able to disinfect their hands as frequently as they like.

As a postscript to this short account of the plan of our grounds those interested in our hospital will be glad to hear that the longer we stop here the more pleased we are with the site. We are not free, of course, from many of the difficulties that beset all the military hospitals out here. For instance, we have to struggle with a very heavy visitation of enteric fever. This, by demanding the services of so many of our male and female staff, throws a severe strain upon our resources, for we have only 100 orderlies to the 160 orderlies of a general military hospital. Our sisters, also, often find it heart-breaking work to sustain the unequal battle against the never-ending invasion of vermin brought down by each train-load from the front. We are harassed, too, by the fact that the supply of milk is precarious and that eggs are extremely scarce. Fruit and fresh vegetables, except potatoes and onions, are absolutely unobtainable. On the other hand, we have many things to be thankful for. Our water-supply, for instance, is unimpeachable. The climate, too, is most healthy, sunny and warm in the day and not yet very cold at night. The distant scenery is distinctly attractive. Our specialists in ophthalmic and dental surgery and in x-ray work have proved a godsend. The same may be said with the utmost truth of our body of nursing sisters which is larger than usual. Nor must our masseur be forgotten. His assistance has been most efficacious in many cases of fractures and stiff joints and withered muscles. Again, it is a great gain that we are able to do all our own washing and that we have a really efficient steriliser which can tackle, even though we are isolated in the Karroo, the otherwise insurmountable difficulty of how to disinfect on a large scale. Last, but by no means least, we owe much to our position of "splendid isolation." For nearly 30 miles on each side of us there are no signs of civilisation except a few ostrich and grazing farms. There are no troops to soil the ground, the water, or the air, except the necessary guard of 50 men. For this reason we suffer less than most similar hospitals from dust. We enjoy an immunity from outside interference which will be readily appreciated by all those who are in a position to realise what an amount of hard work has to be got out of the staff and how easily the harmonious working of a large volunteer staff such as ours is could be upset, or at least hampered, by the existence in our neighbourhood of any factors capable of still further complicating the many interests which have to be considered in the running of such a hospital. Not a few ladies devoted to good works but possessing no technical training have come out to South Africa on purpose to "help in any capacity" in the military hospitals, but the explicit instructions, which we have received from the committee in London for whom we act, no less than the fact that there is not a room which they could hire for their accommodation within 29 miles of us, have saved us from the unpleasant duty which might otherwise have devolved upon us of telling these willing but unwanted souls that after a considerable experience of the value of their kindly meant offers, and after the fullest consideration, we would very much rather have their room than their company.

PS.—Of course, we should not have put the enteric fever patients into the huts so near the operating theatre if we had not been flooded with them before any other accommodation was available, but we have not had cause to regret this proximity.

Deelfontein, May 14th.

(FROM OUR SPECIAL CORRESPONDENT AT THE BASE.)

I mentioned in a previous letter[1] that I had seen a clip of Mauser bullets which had the appearance of being covered with a coating of verdigris. I am happy to be able to state that on being submitted to a thorough analysis this green coating is not verdigris but a mixture of paraffin wax and carbonate of copper which appears to have been used for the double purpose of preventing the cartridge suffering from damp and of supplying a hermetical closing between the brass capsule and the bullet, thus preventing rust of the barrel. This is vouched for by Dr. Impey of Cape Town and I am very glad to be able to put this matter at rest and thus clear up a baseless suspicion of the intentions of our "brother Boer."

The news for the past few weeks has been sufficiently exciting from a military point of view but has proved monotonous in a degree from a surgical aspect. The cases coming down from the front at present are, with very few surgical exceptions, entirely those of enteric fever and dysentery. Of these we have enough and to spare, every few days seeing a large convoy arrive. At present No. 1 General Hospital and No. 2 General Hospital are filled to overflowing. Fortunately, most of the patients are convalescent and simply awaiting passage home, but of course amongst the crowd there are sure to be some who will require careful treatment and nursing for a considerable period before they are put on board. The enteric fever roll of this campaign is likely to be a record one, though I am happy to be able to say that our percentages of recoveries are very satisfactory, which is undoubtedly due to the excellent arrangements that exist for medical treatment and nursing. The fact remains, however, that, with very few exceptions, these men will not be fit for duty for some considerable time. The voyage home is a great factor in their treatment and it rapidly builds up the patients in those cases in which extreme nervous prostration is a pronounced feature, and there are many such. In fact, it is rare to see patients who

[1] THE LANCET, May 5th, 1900, p. 1312.

have had even slight attacks and no complications escape the nervous sequel.

Since my last letter No. 3 General Hospital has been sent up to Kroonstad from Rondebosch and by this time it is in full swing. The hospital was accompanied by 30 nursing sisters, and in its place a convalescent hospital for 500 cases is to be established. Already huts are springing up where tents once stood. The transports have been leaving at frequent intervals with full complements of invalids, both officers and men, and a very great number must have gone home during the past month. The Surgeon-General is at Bloemfontein, and Colonel McNamara (from Gibraltar) has succeeded Colonel W. F. Stevenson as principal medical officer of the lines of communication, the latter being at the front with the headquarters.

I am sorry to say that disease and hard work have been making themselves felt amongst the officers and men of the Royal Army Medical Corps. I hear that two officers have fallen victims to enteric fever at Bloemfontein and that a considerable number are on the sick list; but this was only to be expected—they are but flesh and blood like other men, though some people seem to think that they are machines and can go on for ever without rest or relaxation. This is a grim fallacy that will, I am afraid, have a rude awakening at the end of the war. Let us trust that the lesson may be taken to heart and that a more generous policy may be inaugurated in matters medical in the army of the future.

The winter rains have begun in this colony now and the mornings and evenings are cold and damp, but up-country the rains are over and the climate is charming.

A convalescent sanatorium for officers is to be established at Majesfontein at the end of this month and will relieve the pressure on the Claremont Officers' Hospital which during the past month has been very great.

The hospital ship *Princess of Wales* is lying in Simon's Bay and is, I hear, to be sent up the coast before coming home. She is an object of great curiosity to the inhabitants and is visited by numbers of people, who return amazed at the pitch of perfection attained in her fitting up.

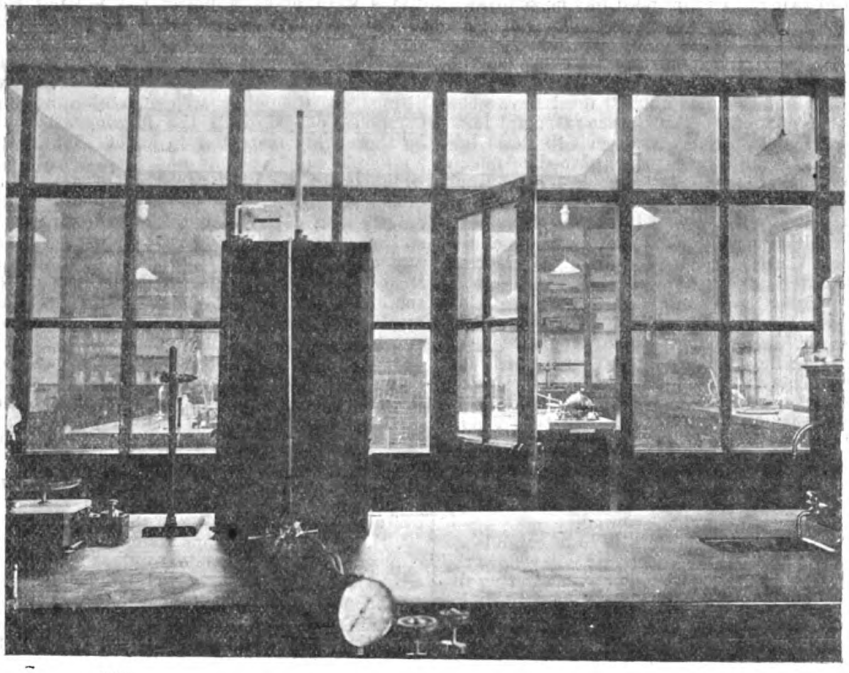
Claremont, Cape Colony, May 23rd.

THE NEW CLINICAL LABORATORIES OF THE WESTMINSTER HOSPITAL.

ON June 12th Lord LISTER presided over the ceremony inaugurated by the governors of the Westminster Hospital for the official opening of the new clinical laboratories which have recently been added to that hospital. The proceedings consisted of a reception in the board room of about 100 guests by Sir John Wolfe Barry (chairman of the House Committee), Dr. W. H. Allchin (senior physician to the hospital), and Dr. W. S. Lazarus-Barlow (pathologist to the hospital).

Sir J. WOLFE BARRY explained that the clinical laboratories had been instituted for the elucidation of disease and thus to assist in relieving the suffering poor. The formation of such a department enabled surgeons and physicians to approach the treatment of disease with absolute scientific knowledge as compared with the greater difficulties that they had in times past.

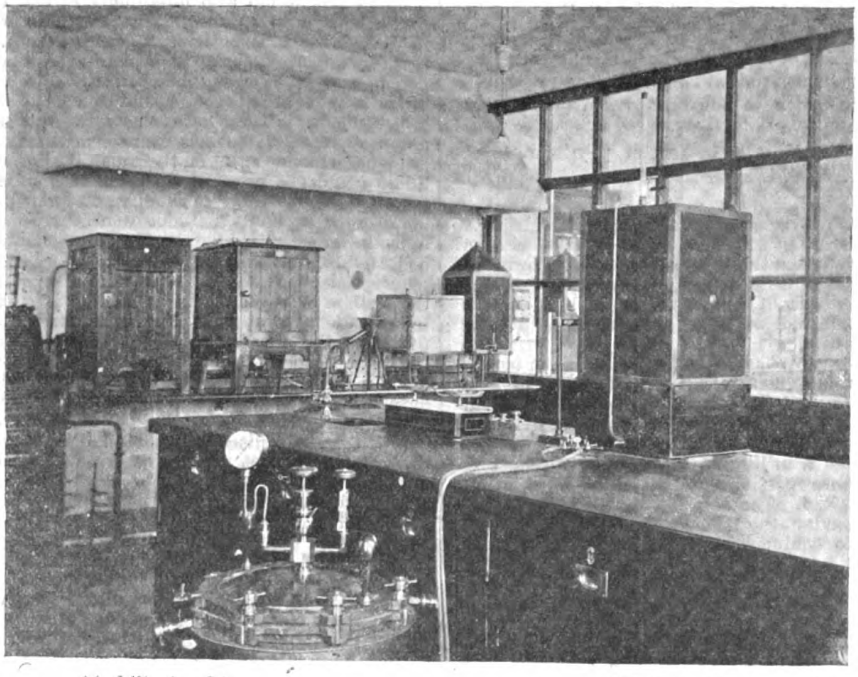
Dr. LAZARUS-BARLOW said that before inspecting the laboratories he would like to call the attention of those present to one or two points of importance. The Westminster Hospital endeavoured to keep abreast of research work so as not only to give the very best chances to the patients, but also, speaking from a utilitarian standpoint, to render the most efficient return possible to the hospital subscribers for the money received. The House Committee had spared no expense in making the laboratories as perfect as possible in regard to equipment. The fundamental requirements in clinical laboratory work were that the bacteriological portion must be divided from the histological portion. It was necessary that the bacteriological investigations should be carried on with an absence of dust, and for that reason the two departments were divided from one another by a glass partition with a swinging door. For histological work light was an important consideration, and as far as natural light was concerned each investigator would be provided with a north light. For artificial light eight pendant electric lamps of 16 candle power had been provided and the walls and the ceilings had been lined with white encaustic tiles. There was an ample supply of hot and cold water and great attention had been paid to the drainage. With the exception of where the drains were actually under the flooring they were open earthenware channels specially constructed and lined with vitreous enamel. Every drain was most carefully trapped and the drainage system of the laboratory was entirely distinct from the hospital drainage. By making the fittings in the cupboards moveable and providing five manholes cut through the flooring all the drains could be thoroughly inspected in about 15 minutes. There was an ample supply of gas and there were 39 electric plugs which could be used for the purposes of motive power or for lighting. He would draw their attention particularly to a cupboard capable of holding 9000 microscopic slides, the idea being to preserve specimens so that any case which returned to the hospital after a lapse of some years could be discussed with the aid of the original sections prepared when the patient first came in. This would afford any observer the opportunity of forming a fresh opinion from the original specimen in case the individual judgment of the original pathologist was not accepted in every detail. All apparatus necessary for clinical work had been procured and was ready for use, but the hospital had not been asked for any funds to pay for research apparatus of a more or less speculative character. The laboratories were of such a kind that it was justifiable for the hospital to pay for their upkeep towards the advancement of scientific research. Dr. Lazarus-Barlow then read a letter of congratulation on the opening of the laboratories from Professor W. H. Welch of the Johns Hopkins University, Baltimore.



A visit was then made to the top floor of the hospital where the laboratories are situated and there Lord Kelvin put in motion a motor to shake some tubercle bacilli in carbolic acid and Lord Lister made a cultivation from some tubercle bacilli derived from the original tubercle discovered by Koch in 1884.

On re-assembling in the board room Lord LISTER gave an address in which he said that the clinical laboratories they had inspected would enable the physicians of the hospital to bring to bear on their cases the most advanced knowledge and the most refined methods of investigation. Many a diagnosis that otherwise would be obscure would be made clear. Successful treatment was directly proportionate to correct diagnosis. He was convinced that the work carried on there would not only benefit the patients in that hospital but would also unfailingly extend the boundaries of knowledge so as to promote the now rapid advance of pathological and therapeutical research. There was another important way in which service would be rendered and that was the powerful means the laboratories would afford for sound practical knowledge to the student. There was now a tendency to look askance at medical schools connected with hospitals and to grudge the money spent on their maintenance and extension. There could not possibly, he conceived, be a greater mistake. Without the opportunity of practical instruction afforded by hospitals the education of the rising generation of medical men would be absolutely impossible, and it might be fairly discussed whether the educational services rendered by hospitals were not of greater importance and benefit to the welfare of the community than their direct advantages to the patients treated in them. He considered it a matter for which the governing body of the Westminster Hospital was to be congratulated, and he thought that the public owed a debt of gratitude to them for wisely and boldly devoting a large sum of money to the creation of these laboratories. He felt sure that before many years were over it would be recognised that these laboratories were amongst the most important means which hospitals could contain of doing good service to the community. Lord Lister concluded with a complimentary reference to the appointment of Dr. Lazarus-Barlow as pathologist to the hospital.

Dr. W. S. CHURCH (President of the Royal College of Physicians of London) said that he would not be in a position to properly treat his patients at the hospital with which he was connected unless he had the advantage of the experimental work in the clinical laboratory. A great charity in the largest sense of the word would be effected by affording facilities for the investigation of disease leading to a decrease in the necessity for so many beds at the hospital.



Sir WILLIAM MACCORMAC (President of the Royal College of Surgeons of England) referred to the creation

FIG. 1.

A general view of the two Laboratories

FIG. 2.

A corner in one of the Laboratories.

of similar laboratories at St. Thomas's Hospital five years ago and said that the greatest possible advantage had accrued in the treatment of the patients, the accuracy of diagnosis lending itself materially to increasing the certainty of success.

In the course of the ceremony the architect of the new buildings, Mr. H. Percy Adams, was introduced to Lord Lister and Lord Kelvin, and the excellence of the work, which was carried out by Messrs. Baird and Tatlock, received special notice.

A vote of thanks to Lord Lister was proposed by Lord KNUTSFORD, a vice-president of the hospital, seconded by Dr. ALLCHIN as representing the medical staff, and supported by Mr. W. G. SPENCER on behalf of the surgical staff.

Lord LISTER briefly replied and the proceedings terminated.

THE ANNUAL MEETING OF THE BRITISH DENTAL ASSOCIATION.

THE British Dental Association celebrated its twenty-first anniversary and held its annual meeting on Saturday, Monday, and Tuesday, June 2nd, 4th, and 5th, in Leeds. At the general meeting held on the first day in the Central Hall of Yorkshire College, the retiring President, Mr. J. H. Mummery read a valedictory address previously to vacating the chair in favour of the new President, Mr. George Brunton.

The treasurer's report which was submitted to this meeting showed that during the year the membership had considerably increased and numbered, at the end of 1899, 1089. The balance shown at the end of the year amounted to £1900. The secretary's report, which dealt principally with legal business and matters of discipline, called attention to a case which arose out of the use of the title "dentist" and the description "dental establishment." The result of the trial was the infliction of a penalty, the presiding magistrate remarking that the case must act as a warning to the defendant and others and that it was the duty of the bench to protect the public and they would do so.

After other business a hearty welcome was given to M. Burt, a delegate from the International Dental Congress to be held in Paris this year. M. Burt cordially invited the members of the British Dental Association to attend that Congress.

Subsequently the meeting was thrown open to visitors and a large number of ladies attended. Alderman JOHN GORDON, the mayor of Leeds, in a humorous speech welcomed the members and visitors to the city, and the PRESIDENT expressed on behalf of the association his thanks to the mayor for this welcome.

In his address the PRESIDENT alluded to the progress which dentistry had made and called to mind some of the great names connected with the dental profession. In the chemical lecture theatre of Yorkshire College during the afternoon several interesting lectures were given, and social gatherings terminated the first day's proceedings.

On the morning of the second day several important papers were read, among them being one by Mr. LLOYD WILLIAMS (London) on the Teaching of Mechanical Dentistry in Dental Schools. This was followed by a long and interesting discussion. The reader of the paper urged that the dental surgeon needed the continual exercise of manual dexterity to a greater degree than in any other branch of surgery and that the conditions required almost microscopic exactitude. Three years in the laboratory, he maintained, was barely time to enable the student to obtain a grasp of his work.

In the afternoon Mr. T. CHARTERS WHITE, the president of the Microscopical Section, gave an address on Photo-micrography, and demonstrations of crown work and other subjects filled the business portion of the time. Later in the afternoon a reception was held in the Medical School in Thoresby-place, and in the evening the annual dinner was held at the Hôtel Métropole. Mr. George Brunton, the President, occupied the chair and among those present were Mr. J. H. Mummery (ex-President of the association), Mr. T. Pridgin Teale, F.R.S., Professor De Burgh Birch (dean of the Yorkshire College Medical Department), Mr. J. Smith Turner, Mr. C. S. Tomes, F.R.S., M. Burt, Mr. T. R. Jessop, Mr. F. Canton, Professor T. Wardrop Griffith, Mr. Storer Bennett (chairman of the representative board of the association), Dr. A. G. Barrs, Dr. E. F. Trevelyan, Dr. J. Spottiswoode Cameron (medical officer of health of Leeds), Mr. T. S. Carter, Dr. T. Churton, Dr. J. F. W. Silk, Dr. J. B. Hellier and Mr. J. F. Pink (secretary of the association).

In responding to the toast of "The City and Trade of Leeds" Alderman HARDING said that he was glad that a school of dentistry for Leeds had been foreshadowed.

Mr. T. R. JESSOP, who proposed the toast of the evening, said he would like to see the British Dental Association amalgamated with the British Medical Association and occupying a position as a section of that association.

Mr. J. SMITH TURNER responded.

With the toast of "The Visitors" the name of Mr. Pridgin Teale was coupled.

In reply Mr. TEALE spoke of the interest taken by the General Medical Council in dental matters and from this he augured good things.

The work during the morning of the third and closing day principally consisted of various demonstrations of practical work in dentistry. In the afternoon the general meeting was continued in the chemical lecture theatre, where Mr. Norman G. Bennett (London) read a paper on the Need for the Recognition of the Association of Dental Surgeons by the War Office and Admiralty. Mr. Bennett said that between the years 1875 and 1885 one in every 138 recruits for the army was rejected on account of defective teeth. At the present time the facilities for obtaining the benefits of conservative dentistry in the service were nearly as meagre as they were 20 years ago, the list of instruments supplied to surgeons at the army station hospitals being quite inadequate for any useful purpose. The instruments supplied to the naval surgeons were certainly better than those given to the army. He contended that the conditions laid down with reference to recruits of both services were unduly severe, and referred to a question recently answered in the House of Commons by Mr. Goschen, who stated that the number of men and boys rejected on account of bad teeth was as large as 25 per cent. Reviewing the conditions prevailing in other countries, Mr. Bennett said that the United States were markedly in advance of other nations. For several years efforts had been made to bring about the appointment of dental surgeons in the army, and a Bill with a likelihood of becoming law was now before the House of Representatives, which provided for the appointment of contract dental surgeons with no rank—or possibly ranking with the civil surgeons who were with the English army in South Africa—to attend to the wants of the soldiers. A discussion followed in which the urgency and need for dental assistance in the services were insisted upon.

Subsequently a motion was carried requesting the Representative Board of the Association to seek steps to further the proposal to provide proper dental aid to the army and navy.

An informal reception by the President at the Hôtel Métropole brought the proceedings of a well-attended Congress to a close.

It was decided to hold the next annual meeting in London in August, 1901, and Mr. S. J. Hutchinson, consulting dental surgeon to University College Hospital, was chosen president-elect.

THE MEDICAL, SURGICAL, AND HYGIENIC EXHIBITION.

(*Continued from p. 1674.*)

FOODS and special foods were well represented and some new food products have been brought forward during the past year which are worthy of consideration. Plasmon, for example, is a cleverly prepared white powder, consisting of the proteids of milk together with the mineral substances, which is soluble almost completely in water. According to our own analysis, which at the present time is not completed, it consists broadly of one-tenth of milk salts and nine-tenths of milk proteid. This interesting preparation has been spoken of so favourably that we are at the present time submitting it to further

analysis in THE LANCET Laboratory, and on the results being obtained we shall be able to describe it more fully. Plasmon is used with advantage in raising the food value of biscuits, beef extract, and chocolate, all of which preparations were exhibited by the Plasmon Syndicate, Limited, of 56, Duke-street, Grosvenor-square, London, W. Messrs. G. Nelson Dale and Co., Limited, of 14, Dowgate-hill, London, E.C., devoted the space on their stall exclusively to the exhibition of specimens of "Hipi," a pure mutton essence. We have shown in our analytical records that this essence possesses a high nutritive value and affords an agreeable change from various beef extracts. It yields a broth of excellent flavour containing pronounced stimulating and nutritious properties. The well-known Milkmaid brand of condensed milk was amongst the exhibits of the Anglo-Swiss Milk Co. of 10, Mark-lane, London, E.C. The specimens included unsweetened, sterilised, and enriched milk known as ideal milk and cocoa, chocolate, and coffee and milk. It is satisfactory to add that this company take care in the preparation of their condensed milk not to eliminate the important article of food milk-fat during concentration. We have before referred to the excellence and convenience in use of Cerebos salt, which is in the condition of fine powder which does not cake through damp and which contains further added phosphates. This preparation was shown by Cerebos, Limited, of Newcastle-on-Tyne and 3, Maiden-lane, London, E.C. The Hovis Bread Flour Company of Macclesfield showed an assortment of their products, the basis of all of which is Hovis flour, which contains the germ of wheat unimpaired. Under the name of "Lemco" the well-known Liebig Company's extract of beef is in future to be known. Its composition and its mode of preparation leave no doubt of its nutritive value and it serves besides as a stimulant to the assimilative processes. The same company (of 9, Fenchurch-avenue, London, E.C.) exhibited specimens of Peptarnis which, as we have shown, contains a high proportion of peptones. It is therefore easily digestible without objectionable flavour and is valuable where weakness of the digestive system exists especially as a sequel of disease. Messrs. Fairchild Brothers and Foster of Snow-hill-buildings, London, E.C., presented to view their well-known food products which are, in the main, so constituted as to be admirably adapted for invalid use or in those cases where digestive capacity is impaired. The exhibit included pure specimens of pepsin and the zymines for producing peptonised milk. Some good meat preparations were shown by Messrs. Cooper and Co. of 80, Gloucester-road, South Kensington, London, W. These included meat-juice, beef essence, chicken, mutton, turtle, and veal essence, which are all supplied in glass jars bearing the distinctive title "Globena." These preparations appear to constitute such an excellent series of easily digestible and nourishing foods that we propose shortly to submit them to analysis in THE LANCET Laboratory. The Manhu Diabetic Foods deserve particular attention, since although they contain the cereal carbohydrates, yet it is stated that these are so broken up as not to affect the diabetic patient in the same manner as starch. Indeed, instances are quoted where these foods apparently have given benefit to diabetic patients. Our own analysis has shown that these foods consist of cereal flour which has been submitted to a process which practically dextrinises the starch. The question remains whether dextrine metabolises in the same way as does starch. It seems to us that this point is worth investigation, but it may be stated that chemically dextrinised starch is even more easily converted into sugar than is starch itself. The evidence of chemistry in the laboratory, however, is not always in accordance with physiological experience. In their published testimonials together with analysis and reports we notice that Messrs. Irving, Son, and Jones, of Liverpool, and of 83, Charing Cross-road, London, W.C., bring forward very little clinical evidence, and it would be more satisfactory if the statements in favour of these foods containing a great percentage of carbohydrates could be confirmed by well-known authorities on glycosuria. These remarks apply with equal force to the Cheltine Foods which are prepared by Worth's Foods Syndicate, Limited, of Cheltenham. These foods contain the derivatives of starch or dextrinised carbohydrates as the result of a special process, so that the proportion of carbohydrates is just the same as in wheaten flour. On the tin of Cheltine Food it is stated that the food cannot be converted into sugar—a statement which is quite incorrect. We have found, as we expected to find, that the food readily yielded sugar on hydrolysis. We repeat that testimonials based on analytical data are of no value whatever. What is wanted is clinical evidence, and clinical evidence alone, and this should not be difficult to obtain. We are glad to find that Messrs. Cadbury Brothers draw attention to the fact that there are strong grounds for objection to the addition to cocoa of certain foreign substances. This resource is quite unnecessary and, indeed, pernicious, especially having regard to the fact that cocoa alone is an excellent food as well as a stimulant, having a salutary action upon the nerve centres. Some excellent specimens of their admittedly pure articles were shown by Messrs. Cadbury Brothers of Bournville, near Birmingham. Milk foods were well represented at the exhibit of M. Henry Nestlé of 48, Cannon-street, London, E.C., the condensed Swiss milk being a notable example of this sort of preparation which contains a maximum amount of butter fat. Milk companies were well represented, especially in the direction of specially prepared milks. A notable example was that of the Aylesbury Dairy Co. of St. Petersburg-place, Bayswater, London, W. Here were shown all kinds of modified milk preparations, comprising sterilised milk and cream, humanised milk, peptonised milk, specially prepared whey, cream milk for infants, milk sugar, and a special sterilised food. The exhibit also included specimens of Koumiss which has been used with advantage in the early stages of phthisis. Excellent also are the milk preparations of the Friern Manor Dairy Farm of 20, Farringdon-street, London, E.C. The humanised milk of this company is prepared by Dr. Gaertner's process which presents special points of advantage, especially in regard to the requirements of infants. The Frame Food Company of Lombard-road, Battersea, London, S.W., showed their well-known extract which contains the nutritive principles of wheat bran, including a large proportion of soluble phosphates. Several food preparations were shown which are enriched with Frame Food, thus raising undoubtedly their nutritive value. Somatose, as we have shown in an analysis from THE LANCET Laboratory, consists practically of albumose derived from the digestion of beef. It is a practically tasteless and odourless powder soluble in water. It is, moreover, a powerful food and is well adapted also as a therapeutic adjuvant where the process of nutrition is feeble. The exhibit which was arranged by the British Somatose Company of 165, Queen Victoria-street, London, E.C., included the interesting compound of somatose with iron which possesses the advantages over the ordinary iron preparations of causing no gastric disturbance or constipation. Messrs. Cosenza and Co. of 95, Wigmore-street, Cavendish-square, London, W., exhibited the Maggi's Consommé and Cross Star soups which have proved so valuable in the preparation of soup for invalids and also for transport purposes, as evidenced by their adoption for hospital use in the present war. Special foods were a feature, also, of the exhibit of Messrs. Callard and Co. of 65, Regent-street, London, W. The specimens included food for the diabetic, food for reducing weight, food adapted for the rheumatic and gouty, and a food for patients in whom the digestive functions are easily disturbed. The Excel Milk Co. of 38, Vauxhall-bridge-road, London, S.W., showed specimens of their sterilised milk. Apart from the efficient process of sterilisation we have shown in our analytical records that the milk is of very high quality. Messrs. J. and G. Cox, Limited, of Edinburgh and Eastcheap-buildings, London, E.C., presented an attractive series of specimens of their "sparkling" gelatin. We have examined this gelatin in THE LANCET Laboratory and were able to report very favourably of this product. It is well adapted for culinary purposes and is convenient also for the making of wine or beef-tea jelly, more especially on account of its purity. A very interesting series of preparations of milk was presented to view by Messrs. Welford & Sons' Dairy Co., Limited, of Elgin-avenue, Maida Vale, London, W. The specimens shown included asses' milk, humanised milk, peptonised milk, ordinary sterilised milk, and sparkling Koumiss. The company carry on their business under strict medical supervision and on lines of organisation in accordance with modern knowledge. They further undertake to prepare modified milk in accordance with the directions which a medical man may think fit to prescribe. The Protene foods have been already fully described in the analytical records from THE LANCET Laboratory in THE LANCET of

Nov. 5th, 1898, p. 1207. Protene food itself is essentially pure milk proteid; its food value is therefore evident. Several food preparations are now made by the Protene Co., Limited, of 36, Welbeck-street, London, W., in which the normal food value is considerably raised by the addition of protene. Messrs. Broomfield and Co. of 83, Upper Thames-street, London, E.C., devoted their stall to the exhibition of specimens of Albene which is described as a pure, highly refined vegetable fat which is suggested as an efficient substitute for cooking purposes for lard, margarine, and butter. One advantage of it is that it does not get rancid. It presents the appearance of purified and refined cocoanut oil. A very interesting series of foods suitable for diabetics, dyspeptics, and invalids was shown by Messrs. G. Van Abbott and Son, of 104, Wigmore-street, Cavendish-square, London, W. The series comprises a selection which should enable the medical man to select exactly what he requires for any particular instance. The gluten loaf seems specially worthy of commendation. The Bovril Company, Limited (152-166, Old-street, City-road, London, E.C.) exhibited many forms of beef preparations, including extracts and raw juices, and a number of preparations of undoubted nutrient character. Indeed, the list of the company's specialities comprises a complete invalid dietary in addition to a number of foods for everyday use. Close by the Bovril preparations was a stall devoted to the exhibition of Virol, which is manufactured by the Bovril Company. As we have pointed out in our analytical records, this preparation presents the composition of not only a complete food, but also of a food containing elements that are readily assimilable.

An exhibit which attracted considerable attention was the Dowsing method of applying radiant heat and light in the treatment of rheumatism. The apparatus consists of a series of elongated electric incandescent lamps placed within reflectors at the side of the bed. By this method, of course, light as well as heat rays are brought to bear upon the patient. The apparatus may be viewed in working order at the offices of the Dowsing Radiant Heat Co., Limited, 24, Budge-row, Cannon-street, London, E.C. The specialities of the Domen Belts Co. of 456, Strand, London, W.C., are well known. Abdominal belts for all kinds of abnormal conditions were shown as well as the "stoop cure" and other appliances. More scientific, perhaps, than many of the other exhibits was that of Messrs. W. Watson and Sons of 313, High Holborn, London, W.C. Here were shown the requisite apparatus and accessories connected with the application of the x rays to medical practice. In addition there were microscopes and microscopical preparations and photo-micrographic accessories. Messrs. Wodderspoon and Co. of 7, Serle-street, Lincoln's Inn, London, W.C., showed an excellent series of temperature-, hour-, and diet-charts. Surgical instruments were well represented in an excellent selection especially adapted to meet the requirements of aseptic surgery by Messrs. Mayer and Meltzer of 71, Great Portland-street, London, W. Surgical instruments were also a feature of the exhibit of Messrs. John Weiss and Son of 287, Oxford-street, London, W., but they showed also some interesting apparatus for the purpose of sterilising both instruments and dressings. Messrs. Pate, Burke, and Co. of 6, Wool Exchange, Basinghall-street, London, E.C., presented to view their excellent surgical and sanitary dressings, the basis of which is Petanelle wool. Petanelle wool, besides being light and highly absorbent, serves also as a check to fermentation and putrefaction—a property which is of decided advantage.

The exhibit included Petanelle disinfecting powder, the absorbent containing the antiseptic and disinfectant being a peat substance. Messrs. Anderson, Anderson, and Anderson, of 37, Queen Victoria-street, London, E.C., showed a number of indiarubber and waterproof materials adapted especially for medical use. This firm is well known for its water-beds, water-cushions, and water-pillows. Mr. Harry Cox of 10, 11, and 28, Cursitor-street, Chancery-lane, London, E.C. undertook the demonstration of x rays with the very latest and best apparatus for the purpose. Examples were shown of x ray outfits supplied by him for the present war. The improved instep arch sock, the invention of Mr. Holland, of 40, South Audley-street, Grosvenor-square, London, W., is now made in three forms—namely, the ordinary sock for moderately flat feet, the low sock for severe cases, and the broad sock for long-standing cases. Besides this appliance, which is well known as an aid in the treatment of flat-foot, other similarly interesting exhibits were shown, such as cork boots for the lame and boots for corns on the soles of the feet. A very useful series of accessories for the use of nurses was submitted for inspection by Mr. William K. Stacy of 4, Newgate-street, London, E.C. It would be impossible in the space at our disposal to mention every individual speciality shown on the well-stocked stall of Messrs. Southall Brothers and Barclay, Limited, of Birmingham. The exhibit included every sort of medical and surgical appliance besides the sanitary preparations to which this firm gives special attention. A very useful little appliance, and one which we have mentioned favourably before, is the Instra Warmer, which was exhibited by Messrs. D. Blair and Co. of 6, Strand-on-the-Green, Chiswick. The principle of this invention—namely, that depending upon the slow combustion of a charcoal rod—is now applied not only to pocket-warmers but to chest-warmers, foot-warmers, food-warmers, and to ankle-straps also. The chief features of the exhibit of Messrs. S. Maw, Son, and Thompson, 7 to 12, Aldersgate-street, London, E.C., were perhaps the aseptic instruments and dressings, but there were besides a great number of recent surgical and medical appliances which afforded an interesting subject of inspection for medical men. The patent appliances for the lame made by the O'Connor Extension Company, of 2, Bloomsbury-street, London, W.C., are well known. It is worthy of remark that the appliances of this company were accepted by the War Office for use in South Africa.

Sanitary appliances and preparations are a distinct feature of this exhibition, but this year the space devoted to this section seemed to be smaller than on the previous occasion. Probably the sanitary appliance which first attracted the attention of the visitor as he entered the hall was the Blackburn Electric Fan and Motor. Doubtless the air in the building owed its freshness to this ventilator. The three fans employed for the purpose were supplied by the Blackburn Ventilating Co. of 63, Fore-street, London, E.C. The stall of Messrs. A. Boake, Roberts and Co. of Stratford, E., was devoted chiefly to specimens of sulphur dioxide for fumigation purposes. The gas liquefied by cold and pressure is contained in cylinders. The exhibit also included a fluid preparation of phenol called "Lozar." In a more or less solid form a special wood fibre is employed for absorbing it which possesses advantages for this purpose. A very comprehensive series of disinfectant preparations the composition of which is based mostly on Sanitas was shown by the Sanitas Co., Limited, of Bethnal-green, London, E. The exhibit included, however, some other disinfectant and antiseptic preparations. The chief advantage of Sanitas is that while it is a distinct and efficient disinfectant it is very agreeable by reason of its pleasant pine-like smell. The exhibit of Messrs. J. Defries and Sons of 147, Houndsditch, London, E.C., afforded an opportunity of demonstrating three interesting and, we may add, scientific appliances. These were several forms of the Pasteur-Chamberland Filter, an illustration of the equifex disinfecting apparatus, and Scurfield's simple ventilation indicator. The last-named instrument affords a quick and fairly accurate way of estimating the carbonic acid in the air, the process being based on the classic method of Pettenkofer. According to the results of experiments quoted by Messrs. Newton, Chambers and Co. of Thorncliffe (near Sheffield) and 331, Gray's Inn-road, London, W.C., Izal is an effective germicide, and it is stated that over 9,000,000 gallons of this fluid have been ordered for the use of the army in South Africa. Medical Izal is said to be four times as powerful as a germicide as absolute phenol and is also said to be non-poisonous and non-corrosive. The exhibit included preparations of Izal such as lint, wool, gauze, lozenges, "perles," &c. Messrs. Major and Co. of Sculcoates, Hull, exhibited chiefly their Eucryl preparations. Eucryl itself is a very agreeable and powerful antiseptic and disinfecting fluid. We have dealt with its composition in the Analytical Records of THE LANCET Laboratory. The Berkefeld Filter Company of 121, Oxford-street, London, W., gave a demonstration of their well-known filters, the tubes of which are composed of a specially prepared *kieselguhr*. The advantage of these filters is that while they are rapid in action they yield a sterile filtrate. Jeyes' disinfectant fluids have now been a long time before the public and on all sides excellent reports have come to hand of their germicidal activity. The exhibit of the company (of 64, Cannon-street, London, E.C.) contained a great number of creolin compounds and preparations.

A variation in the *tout ensemble* of the exhibits just

described is afforded by mineral waters and other beverages, which, moreover, are not without medical interest. For example, the Bellawattee Company, of 244, Oxford-street, London, W., exhibited a great number of patterns of their patent teapot which provides against an excessive amount of tannin entering into the infusion of tea. The device is quite simple and effectual. Stower's lime-juice cordial and clarified lemon-squash were the two specialities exhibited by Messrs. Alexander Riddle and Co., of 36 and 38, Commercial-street, London, E. The wholesomeness of these preparations and their adaptability for the easy production of a beverage are established, the materials used being of the best kind and no objectionable ingredients being added. We have been able to speak in favour of the purity of these preparations in our analytical records, but the case is somewhat overstated, we think, when the manufacturers assert that the cordial "materially assists the digestion and is practically invaluable to dyspeptic dispositions." Specimens representing the various natural mineral waters of Vichy and Carlsbad were shown by Messrs. Ingram and Royle, Limited, of 26, Upper Thames-street, London, E.C. The exhibit also included bottles of Hunyadi Janos, a natural aperient water which was exhaustively dealt with by THE LANCET Special Analytical Commission on Natural Mineral Waters in THE LANCET of Dec. 5th, 1896, p. 1622. Lastly may be added the medicated wines of Messrs. Stephen Smith and Co., of Malmesbury-road, Bow, London, E. These included an excellent coca wine prepared from the leaf and therefore not containing the chemically prepared alkaloid; keystone beef wine; and keystone burgundy—preparations of distinct merit as we have already shown in our analytical columns.

There were also exhibited a selection of objects of interest to the medical man but of a miscellaneous character, as exemplified in the medical books, charts, and diagrams shown by Messrs. John Bale, Sons, and Danielsson, of 83, 85, 87, and 89, Great Titchfield-street, Oxford-street, London, W. Again, several typewriters were exhibited possessing some novelty; amongst these were the instrument of the Oliver Typewriter Co., 42, Poultry, E.C., and that of the Williams Typewriter Co., of 104, Newgate-street, London, E.C. Lastly, the Blickensderfer typewriter attracted some attention, since it may be fitted with a special wheel for writing medical prescriptions. The machine may be inspected at 9, Cheapside, London, E.C. Many of the stalls were devoted to the exhibition of new publications. Amongst the publishers represented were Messrs. Rebman, Limited, of 129, Shaftesbury-avenue, London, W.C., Messrs. John Bale, Sons, and Danielsson, 83, 85, 87, and 89, Great Titchfield-street, Oxford-street, London, W., and the Scientific Press, Limited, of 28 and 29, Southampton-street, Strand, London W.C.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 5473 births and 3748 deaths were registered during the week ending June 9th. The annual rate of mortality in these towns, which had been 18·4 and 17·7 per 1000 in the two preceding weeks, further declined to 16·8 last week. In London the death-rate was 15·9 per 1000, while it averaged 17·5 in the 32 provincial towns. The lowest death-rates in these towns were 8·0 in Birkenhead, 11·4 in Swansea, 12·1 in Derby and in Burnley, and 12·3 in Croydon; the highest rates were 19·9 in Sheffield, 21·3 in Salford, 23·1 in Manchester, and 24·8 in Liverpool. The 3748 deaths in these towns included 386 which were referred to the principal zymotic diseases, against 443 and 423 in the two preceding weeks; of these, 128 resulted from measles, 111 from whooping-cough, 65 from diphtheria, 30 from scarlet fever, 27 from diarrhœa, 24 from "fever" (principally enteric), and one from small-pox. The lowest death-rates from these diseases last week occurred in Norwich, Nottingham, Birkenhead, Huddersfield, and Newcastle; and the highest rates in Cardiff, Derby, Oldham, and Blackburn. The greatest mortality from measles occurred in Bristol, Cardiff, Derby, and Sunderland; from whooping-cough in Liverpool, Manchester, Oldham, and Gateshead; and from diarrhœa in Blackburn. The mortality from scarlet fever and from "fever" showed no marked excess in any of the 33 towns. The 65 deaths from diphtheria included 24 in London, seven in Leeds, six in Leicester, four in Cardiff, and four in Sheffield. One fatal case of small-pox was registered last week in Oldham, but not one in any other of the 33 large towns. There were 11 small-pox patients under treatment in the Metropolitan Asylums Hospitals at the end of the week, against three, five, and seven on the three preceding Saturdays; four new cases were admitted during the week, against three and four in the two preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, June 9th, was 1754, against 1784 and 1759 at the end of the two preceding weeks; 203 new cases were admitted during the week, against 221, 216, and 194 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 417 to 266 in the five preceding weeks, rose to 268 last week, but were slightly below the corrected average. The causes of 52, or 1·4 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Nottingham, Bolton, Oldham, and in 10 other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Birmingham, Liverpool, Blackburn, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·6 and 18·6 per 1000 in the two preceding weeks, further declined to 18·3 during the week ending June 9th, but exceeded by 1·5 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 13·3 in Paisley and 15·8 in Aberdeen to 19·9 in Glasgow and 21·5 in Greenock. The 564 deaths in these towns included 19 which were referred to measles, 17 to whooping-cough, seven to diarrhœa, six to scarlet fever, five to "fever," and three to diphtheria. In all 57 deaths resulted from these principal zymotic diseases, against 65, 76, and 73 in the three preceding weeks. These 57 deaths were equal to an annual rate of 1·9 per 1000, which was 0·2 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The deaths from measles, which had been 10 and 16 in the two preceding weeks, further rose last week to 19, of which 14 occurred in Glasgow and four in Edinburgh. The fatal cases of whooping-cough, which had been 36 and 25 in the two preceding weeks, further declined to 17 last week, and included 14 in Glasgow and two in Aberdeen. The deaths from diarrhœa, which had increased from nine to 25 in the four preceding weeks, declined again last week to seven, of which four were registered in Glasgow and two in Dundee. The fatal cases of scarlet fever, which had been seven, three, and one in the three preceding weeks, rose again to six last week and included four in Glasgow and two in Paisley. The deaths referred to different forms of "fever," which had been six, two, and one in the three preceding weeks, rose again last week to five, of which four occurred in Glasgow, where two of the three fatal cases of diphtheria were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 84, 94, and 104 in the three preceding weeks, further rose last week to 106, and were 13 in excess of the number in the corresponding period of last year. The causes of 24, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·2 and 21·9 per 1000 in the two preceding weeks, rose again to 23·1 during the week ending June 9th. During the past four weeks the death-rate in the city has averaged 23·3 per 1000, the rate during the same period being 16·4 in London and 18·4 in Edinburgh. The 155 deaths belonging to Dublin registered during the week under notice were eight in excess of the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against nine, five, and three in the three preceding weeks; of these, five resulted from whooping-cough, two from diphtheria, two from diarrhœa, one from "fever," and not one either from small-pox, measles, or scarlet fever. These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 1·6 in London and 1·2 in Edinburgh. The fatal cases of

* Including 25 cases of membranous croup.

† Including deaths from membranous croup.

whooping-cough, which had been one, three, and none in the three preceding weeks, rose again to five last week. The two deaths from diphtheria showed an excess over the average of recent weeks. The fatal cases of diarrhœa, which had been two, none, and one in the three preceding weeks, rose to two last week. The mortality from "fever," corresponded with that in the preceding week. The 155 deaths in Dublin last week included 29 of infants under one year of age and 23 of persons aged upwards of 60 years; the deaths of infants were equal to the number recorded in the preceding week, but the deaths of elderly persons showed a considerable decline. Eight inquest cases and four deaths from violence were registered; and 60, or nearly two-fifths, of the deaths occurred in public institutions. The causes of 12, or nearly 8 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING MAY, 1900.

IN the accompanying table will be found complete statistics relating to sickness and mortality in each of the 43 sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 7·2 per 1000 of the population, estimated at 4,589,129 persons in the middle of the year. In the three preceding months the rates had been 7·0, 6·6, and 6·2 per 1000 respectively. The rates were considerably below the average in Paddington, Kensington, St. George Hanover-square, Hampstead, St. Martin-in-the-Fields, and Rotherhithe; while they showed the largest excess in City of London, Whitechapel, St. George in the East, St. Saviour Southwark, St. George Southwark, and Plumstead sanitary areas. Nine small-pox cases were notified during May, of which two belonged to Kensington, two to Marylebone, and one each to Chelsea, St. George Hanover-square, Shoreditch, St. George-in-the-East, and Mile End Old Town sanitary areas; seven small-pox patients were admitted into the Metropolitan Asylums Hospitals during May, and seven remained under treatment at the end of the month. The prevalence of scarlet fever showed a further slight increase upon that recorded in recent months; among the various sanitary areas this disease was proportionally most prevalent in City of London, Whitechapel, St. George-in-the-East, St. Saviour Southwark, St. George Southwark, and Plumstead. The Metropolitan Asylums Hospitals contained 1735 scarlet fever patients at the end of May, against 1827, 1654, and 1619 at the end of the three preceding months; the weekly admissions averaged 198, against 152, 162, and 174 in the three preceding months. The prevalence of diphtheria showed a marked increase upon that in the preceding month; the proportional prevalence of this disease was greatest in City of London, Bethnal Green, St. George in the East, St. Saviour Southwark, Bermondsey, and Plumstead sanitary areas. There were 1209 diphtheria patients in the Metropolitan Asylums Hospitals at the end of May, against 1402, 1236, and 1131 at the end of the three preceding months; the weekly admissions averaged 172, against 165, 148, and 135 in the three preceding months. The prevalence of enteric fever in London showed a continued decrease from that recorded in recent months; among the various sanitary areas this disease was proportionally most prevalent in Westminster, St. Martin in the Fields, Poplar, Bermondsey, Rotherhithe, and Lee. The Metropolitan Asylums Hospitals contained 176 enteric fever patients at the end of May, against 274, 263, and 208 at the end of the three preceding months; the weekly admissions averaged 24, against 40, 36, and 27 in the three preceding months. Erysipelas was proportionally most prevalent in Marylebone, St. Giles Holborn, St. Luke, St. George-in-the-East, and St. George Southwark sanitary areas. The 20 cases of puerperal fever included three in Hackney, and two each in St. Pancras, Islington, Poplar, and Plumstead sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the public institutions of London having been distributed among the sanitary areas in which the patients had previously resided. During the five weeks ending June 2nd the deaths of 7283 persons belonging to London were registered, equal to an annual rate of 16·6 per 1000, against 20·4, 19·1, and 20·2 in the three preceding months. The lowest death-rates last month in the various sanitary areas were 10·2 in Hampstead, 11·1 in Stoke Newington, 12·3 in St. George Hanover-square, 12·8 in Lee, 13·1 in Camberwell, and 13·2 in Wandsworth; the highest rates were 22·5 in St. George Southwark, 22·8 in Limehouse, 23·9 in St. Luke, 24·0 in City of London, 24·9 in St. Saviour Southwark, and 28·2 in Holborn. During the five weeks of May 775 deaths were referred to the principal zymotic diseases in London; of these, one resulted from small-pox, 299 from measles, 29 from scarlet fever, 129 from diphtheria, 230 from whooping-cough, 38 from enteric fever, and 49 from diarrhœa. These 775 deaths were equal to an annual rate of 1·8 per 1000, against 1·8, 1·7, and 1·8 in the three preceding months. The lowest death-rates from these diseases last month occurred in Fulham, Chelsea, St. George Hanover Square, Hampstead, Stoke Newington, St. Martin-in-the-Fields, and Lee; and the highest rates in Hammersmith, Holborn, Clerkenwell, Limehouse, St. Saviour Southwark, and Rotherhithe sanitary areas. The fatal case of small-pox belonged to Marylebone sanitary area. The 299 deaths from measles were 94 below the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Kensington, Hammersmith, Holborn, Clerkenwell, St. Luke, and Mile End Old Town sanitary areas. The 29 fatal cases of scarlet fever showed a decline of 47 from the corrected average number; the greatest proportional fatality from this disease occurred in City of London, Shoreditch, St. George Southwark, Newington, Rotherhithe, and Woolwich. The 129 deaths from diphtheria were 55 below the average number in the corresponding periods of the ten preceding years; among the various sanitary areas this disease was proportionally most fatal in Islington, Strand, St. George in the East, St. Saviour Southwark, Newington, and Plumstead. The 230 fatal cases of whooping-cough showed a decline of 86 from the corrected average number; this disease showed the highest proportional fatality in Strand, Holborn, Clerkenwell, Limehouse, Battersea, Bermondsey, and Rotherhithe sanitary areas. The 38 deaths referred to enteric fever were slightly in excess of the average number in the corresponding periods of the ten preceding years; among the various sanitary areas this disease was proportionally most fatal in Westminster, St. Martin in the Fields, St. George in the East, Poplar, Bermondsey, and Battersea. The 49 fatal cases of diarrhœa showed a marked decline from the corrected average number; the greatest proportional fatality from this disease was recorded in Marylebone, Strand, Holborn, St. Luke, Shoreditch, and St. George Southwark sanitary areas. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during May was more than 26 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 120 per 1000. The lowest rates of infant mortality were recorded in Hampstead, St. Giles, Strand, St. Luke, St. George-in-the-East, and St. Olave Southwark sanitary areas; and the highest rates in Westminster, Holborn, Clerkenwell, City of London, Limehouse, and St. Saviour Southwark.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: M. H. Knapp to the *Doris* and S. T. Reid to the *Gleaner*.

ROYAL ARMY MEDICAL CORPS.

Major James McM. Bolster, from half-pay, to be Major, with precedence next below C. J. Addison, vice T. A. P. Marsh, deceased. The undermentioned Surgeons on probation to be Lieutenants:—Charles Henry Carr, Edmund Bennett, Francis Pius Lauder, Arthur Charles Adderley, John Tobin, George Edward Leary, and Herbert Ernest Weston. Lieutenant-Colonel Henry J. Michael retires on retired pay in consequence of ill-health. Surgeon-Captain A. Mifsud, Royal Malta Artillery, is granted the temporary rank of Captain whilst serving in Egypt.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Henry John MacKay, 2nd Volunteer Battalion the Wiltshire Regiment, to be Surgeon-Captain; Surgeon-Captain W. J. Harnett to be Surgeon-Major.

VOLUNTEER MEDICAL STAFF CORPS.

The Woolwich Companies: Mowbray Taylor to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 2nd Hampshire (Southern Division, Royal Garrison Artillery): Herbert Fox to be Surgeon-Lieutenant. *Rifle:* 1st Dumbartonshire: William Buchan Armstrong to be Surgeon-Lieutenant. 1st Volunteer Battalion the Highland Light Infantry: Surgeon-Lieutenant P. F. Shaw to be Surgeon-Captain. 2nd Volunteer Battalion the Worcestershire Regiment: Herbert Bree Emerson to be Surgeon-Lieutenant. 2nd Volunteer Battalion the East Yorkshire Regiment: Surgeon-Lieutenant H. J. C. Godfrey resigns his commission.

VITAL STATISTICS OF THE GERMAN NAVY.

The statistical information contained in the subjoined table has been compiled from the official returns issued by the medical department of the Imperial German Navy.

From April 1st to March 31st.	1895-96.	1896-97.
Average strength	21,477	21,675
Admitted (per 1000)	847·6	860·6
Discharged to duty (per 1000)	706·8	716·8
Died in hospital (per 1000)	1·4	0·9
Invalided (per 1000)	116·5	115·5
Remaining (per 1000)	22·9	27·4
Number constantly sick (per 1000)	37·2	39·8
Average duration of cases (days)	14·5	15·3
Total death-rate (per 1000)	4·8	2·9
General diseases (per 1000)	61·3	64·9
Infectious (per 1000)	26·4	29·9
Infectious (Foreign Service) (per 1000) *	98·0	101·5
Infectious diseases, Home Waters (per 1000) *	5·0	5·7
Infectious diseases, African Stations (per 1000) *	268·3	368·3
Infectious diseases, Pacific Stations (per 1000) *	205·0	457·4
Infectious diseases, enteric fever (per 1000)	0·5	1·8

	1895-97.
Infectious diseases, dysentery (per 1000)	0·4
Infectious diseases, intermittent fever (per 1000)	23·5
Infectious diseases, influenza (per 1000)	10·1
Infectious diseases, phthisis pulmonalis (per 1000)	2·9
Infectious diseases, hæmoptysis (per 1000)	0·7
Diseases of respiratory system (per 1000)	100·2
,, circulatory ,, (per 1000)	26·7
,, digestive ,, (per 1000)	123·1
Ophthalmic diseases (per 1000)	38·9
Venereal ,, (per 1000)	133·0

* Local strength.

The deaths from disease during the two years were caused as follows: enteric fever, 8; dysentery, 3; intermittent fever, 4; influenza, 3; sunstroke, 3; pneumonia, 10; pleurisy, 6; phthisis pulmonalis, 13; circulatory affections, 6; other diseases, 24; total 80. The deaths from accidents amounted to 72, and there were 15 suicides—11 occurring in the commissioned ranks. Throughout the biennium the navy remained free from cholera, yellow fever, and small-pox; the immunity from the last-named scourge being unquestionably due to careful revaccination. The considerable prevalence of venereal affections is ascribed to the absence of supervision at foreign ports, especially those under English control. In conclusion, Dr. Wilm points with pride to the fact that during the period under report there were less sickness and mortality in the German navy than in any other. The only blot seems to have been a local but severe outbreak of follicular conjunctivitis which was due to the incautious acceptance of two recruits from Western Prussia who were suffering from granular lids.

TRANSVAAL WAR NOTES.

A field hospital, composed entirely of volunteers, has embarked on the *Tagus* for duty with the Rhodesian field force. The *Daily Telegraph* states that "this is the first mounted field hospital sent out."

With the object of relieving the pressure on the accommodation at the Military Hospital, Devonport, caused by the frequent arrivals of the sick and wounded soldiers from South Africa, a field hospital of 50 beds has been established at Staddon Heights, Plymouth, under the charge of Lieutenant-Colonel J. W. Belcher, R.A.M.C.

Of the 300 invalid soldiers who arrived at the Royal Military Hospital a fortnight ago less than 20 now remain, the rest having been discharged on furlough. On June 6th another party of over 200 arrived under the medical charge of Civil Surgeon Blackiston.

The General of Communications, Cape Town reports that Captain Smithson, R.A.M.C., was discharged from hospital for duty during the week ending May 27th

THE ROYAL ALBERT HOSPITAL, DEVONPORT.

On June 9th Princess Henry of Battenberg laid the foundation stone of the new Nurses' Home and other buildings of the Royal Albert Hospital, Devonport. At the hospital gate Her Royal Highness was received by members of the Reception Committee, which included Lord St. Levan, Admiral Cardale, and Mr. J. May and Mr. T. Leah, who represented the medical staff. The Royal Albert Hospital, which has been doing a most useful work for nearly 40 years, was named after the late Prince Consort by his permission, and he expressed a wish to lay the foundation stone, but unfortunately His Royal Highness died shortly after his desire was made known.

TRANSVAAL WAR CASUALTIES.

The following, attached to the Royal Army Medical Corps, are reported seriously ill at Kroonstad:—Civil Surgeon R. W. Jameson and Civil Surgeon Robertson.

Civil Surgeon H. Bryant, R.A.M.C., died from enteric fever at Bloemfontein on June 7th.

Major Hathaway, R.A.M.C., has been severely wounded in the recent operations near Pretoria.

In connexion with the scheme for the introduction into barracks in India of punkah-pulling by mechanical agency an additional sum of Rs.40,000 has been sanctioned, and the Government of India has called for a full report at the close of the hot weather on the various systems tried.

Correspondence.

"Audi alteram partem."

THE CANNON-STREET HOTEL MEETING AND DR. GLOVER.

To the Editors of THE LANCET.

SIRS,—With the permission of the chairman of the Beckenham and Penge Medical Society I forward the following correspondence for publication. Trusting you will kindly find room for it,

I am, Sirs, yours faithfully,

J. G. GLOVER.

BECKENHAM AND PENGE MEDICAL SOCIETY.

Oakwood-avenue, Beckenham, June 6th, 1900.

DEAR DR. GLOVER,—At a recent meeting of the Beckenham and Penge Medical Society Dr. Sturges, who was present as one of the delegates of the society at the meeting held at the Cannon-street Hotel to protest against the Midwives Bill at present before Parliament, reported what had taken place at that meeting and referred in terms of strong disapproval to the general management of the meeting and in particular to the motion which was brought forward by Dr. Lorimer Hart with reference to yourself just before the close of the meeting when only a few gentlemen were present. This society assisted the Corporate and Medical Reform Association and other societies in organising the Cannon-street meeting and our delegates went prepared to submit some very carefully considered alterations in the Midwives Bill which they hoped might render it a useful measure and one which would safeguard the public and be acceptable to the general practitioner. In consequence of the manner in which the meeting was conducted, the

Beckenham and Penge Medical Society have under consideration the desirability of severing their connexion with the Corporate and Medical Reform Association, and this they will doubtless do at their next general meeting. Meanwhile, I am directed to express to you the deep regret we all feel at the action taken at the meeting with regard to yourself and to assure you of our continued confidence and esteem.

I remain, dear Dr. Glover, yours very truly,
F. ALEX. BARTON, Honorary Secretary.

25, Highbury-place, N., June 8th, 1900

DEAR MR. BARTON,—I am much obliged to you and your society for the expression of your views touching the Cannon-street Hotel meeting and its action towards myself. It is impossible that we should agree on all details of a question so complicated as that of midwives, but I believe the agreement is deeper than is thought, and it will be much promoted by generously construing each other's views of the best way to attain the end we all aim at—the saving of the life of poor lying-in women and securing for all serious midwifery the advantage of medical attendance. Kindly convey to your society my best thanks and believe me, Yours very truly,
J. G. GLOVER.

F. Alex. Barton, Esq., B.A., L.R.C.P. Lond., &c.

THE TREATMENT OF RECENT SPRAINS AND DISLOCATIONS.

To the Editors of THE LANCET.

SIRS,—I am pleased that such an eminent authority as Mr. W. H. Bennett[1] has corroborated the soundness of the treatment of recent dislocations and sprains which I advocated in THE LANCET in 1898.[2] For over 10 years I have treated those and similar lesions by massage and movement, both active and passive, and I have never once had cause to regret my actions. My chief reason for writing to you two years ago, as it is now, was to try to influence medical men to treat such lesions in a way that weakness and stiffness could not remain. It is a notorious fact that bonesetters make their living and their widespread reputations by such cases falling into their hands. Since I have treated my cases in the way which I described in THE LANCET two years ago I have never had the annoyance of an irregular practitioner interfering with any of my uncompleted cases.

I am, Sirs, yours faithfully,
WM. DOIG, M.D. Edin.

Galashiels, N.B., June 9th, 1900.

"ON THE RELATIVE VALUE OF SYMPTOMS OF ACUTE PERITONITIS."

To the Editors of THE LANCET.

SIRS,—I have read Mr. Stanmore Bishop's admirable article on the Relative Value of Symptoms of Acute Peritonitis, published in THE LANCET of June 9th, and should like to endorse almost all that he has written. There are the very widest differences of opinion among practitioners as to the presence or absence of acute peritonitis in cases in which interference is required; and the teaching almost deserves the term which Mr. Stanmore Bishop has applied to it. But I fear even muscular rigidity is not an absolute criterion. It is scarcely more certain than the rest. I have watched throughout a case of acute septic peritonitis which proved fatal within five days in which the abdomen was from first to last perfectly soft, without a trace of muscular rigidity. And if not characteristic muscular rigidity, at least a very close imitation of it is often present in cases of abdominal cramp in which there is no suspicion of inflammation. There is, in fact, no single characteristic symptom of acute peritonitis which is present invariably in all cases alike. All of them are wanting sometimes, and the sooner this fact is recognised the more readily will the diagnosis be made. Muscular rigidity is one of the most constant, but its constancy is not absolute.

I am, Sirs, yours faithfully,
Wimpole-street, W., June 11th, 1900. C. MANSELL MOULLIN.

[1] THE LANCET, June 2nd, 1900, p. 1569.
[2] THE LANCET, Feb. 2nd, 1898, p. 465.

MEAT-SUPPLY OF CARDIFF.—The Cardiff Health Committee on June 1st considered the allegation that inferior meat was sold in the local market. A sub-committee had been appointed to go into the whole question, and after a thorough investigation they agreed with the statements and recommended the appointment of an additional inspector who should be a practical butcher thoroughly conversant with the trade. After a considerable discussion the Health Committee passed a resolution requesting the medical officer of health to draw up a list of the duties necessary to ensure efficient inspection.

THE UNIVERSAL EXHIBITION AT PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

An Unparalleled Number of Visitors.—Order Reigns.—The Exhibition is Ready.

To have visited the Exhibition when it opened in April, and even during the earlier part of May, and then to return again at the commencement of June is to experience sensations that can be compared with the delightful feeling of freshness and calm that follow after a summer storm. The wagons, carts, railway trucks; the drivers, porters, labourers, masons, and workmen, have disappeared. The hurry and bustle are over. The loud, and sometimes angry, cries of those who were struggling to hasten on the work are now replaced by the satisfied voices, the murmurs of admiration from the vast crowds of spell-bound visitors. The sharp stones that cut the feet, the deep ruts made by heavy carts, the pitfalls, the planks and rafters, the empty packing-cases with their sharp protruding nails, have all been removed and safe, dry, and smooth gravel walks greet us on all sides. To the clouds of white chalk and plaster dust has succeeded the sweet air from numerous beds of beautiful flowers or artistically devised clusters of trees and shrubbery. Here and there large palm trees wave their plume-like branches as if to salute the visitors. The air comes fresh and clear from the well-watered verdure and the loudest noises are those of laughter, exclamations of delight and surprise, or of some strange music from a gipsy band or a group of Orientals, negroes and Arabs, rhythmically beating their tomtoms or giving weird expression on deep-toned flutes to an indefinable melody that recalls the nomadic life of the dwellers of the desert. In a word, the Exhibition is now complete. Here and there may be belated exhibitors whose installations are not yet quite in order, but these are so few, far between, and exceptional that they are but as minute specks on the vast and magnificent picture that invites the admiration of the whole world. The promise made has been fully kept. The Exhibition has been completed earlier in the year than any of the preceding universal exhibitions. Nor have the public been slow to acknowledge this fact. Already the number of admissions has beaten all previous records, for there were more than half a million visitors both on Whit-Sunday and on Whit-Monday; and since then even on the ordinary weekdays the admissions have exceeded 200,000. Indeed, it is anticipated that in the height of the season the crowds will exceed the limits of safety. Consequently all the entrances have been connected by telephone to a central office. Here, hour by hour, messages are received from each gate, additions made, and a record is kept as to the number of people actually within the Exhibition. Should this number exceed a certain fixed maximum then the gates will be closed for a while so as to prevent too great a crush. This is a wise and necessary precaution. Even as matters now stand, those who are not satisfied with merely walking round but want to examine minutely some of the exhibits had better devote the morning to serious study. They will then have elbow-room and better opportunities for talking to the exhibitors and for obtaining information. This doubtless involves lunching within the Exhibition, where the restaurants are naturally a good deal dearer than in the town; but as the admission ticket is sold at a discount and can now be obtained for 6*d*., it is no great loss to leave the Exhibition for meals and there are numerous cheap restaurants outside. Wealth is more evenly distributed in France, there are not so many large fortunes as in England, therefore the greater part of the catering is done for that very numerous class of thrifty people who know how to live well for a small expenditure. It is a happy country for those who possess a modest competency and the fear of spending too much need not deter such from visiting the Paris Exhibition.

THE PAVILION OF THE TOWN OF PARIS.

The more frequent the visits to the Exhibition and the more careful the examination of the wonders displayed, the more hopeless the task of description becomes. The details are of such absorbing interest and of such widespread importance that the difficulty is to know what to leave out, what to cut down to a few sentences—in fact, to use a Parliamentary idiom, how best to massacre the innocents. Take as an

example the exhibits of the town of Paris. We are all the guests of this beautiful capital and naturally anxious to know how the town is governed. Besides, it is the second largest metropolis in Europe and certainly the most beautiful and attractive, so that there must be much to learn concerning its methods of administration. Finally, the municipal authorities have organised a unique exhibition where every detail of their administrative work is set forth in a most graphic, realistic, and intelligible manner. But it is not a letter or two, it is a volume, and a very big and a very useful volume, that could be written on this one single exhibit. The pavilion of the town of Paris is situated on the right bank of the Seine, close to the Pont des Invalides, and faces the magnificent Italian Palace that is on the opposite side of the river. Entering by the door nearest to the bridge, the first rooms to the left contain exhibits that relate to the history of Paris. There are quaint edicts dating back some centuries and concerning the government of the town, pictures of old Paris, and some remarkable historical curiosities, including the cradle of the King of Rome, lent by the Emperor of Austria because it was the work of the celebrated Parisian bronze-chasers Odiot and Thomire. On the right hand side of the entrance there are first of all the exhibits of the Paris Municipal Laboratory, where, however, the Ravachol bombs, explosive sardine boxes, and other anarchists' contrivances are not shown; yet this laboratory is best known to the general public as the place where suspicious parcels are examined in case they contain explosives. But, needless to say, the real work of the laboratory is of a much more serious character, though it attracts less public attention. Indeed, it has always been a source of trouble with sanitary reformers that the public will take the greatest interest in an explosion of dynamite that as often as not does no harm at all, while an outbreak of disease which brings many thousands prematurely to the grave fails to awaken public attention. Dynamitards provide more sensational news for the papers than the studies of bacteriologists; but in this Exhibition all honour is rendered to the latter and nothing is said about the former. The Paris Municipal Laboratory is proud of its bacteriological researches, and for this purpose has a special department called the "Salle de Pasteur." It shows photographs of colonies of the bacillus coli and isolated bacilli, of the typhoid bacillus, micrographic photographic apparatus, Dr. Roux's culture stove, and other aids to bacteriology. M. Ogier has an apparatus for taking samples of water. The bottle stands on a heavy slab of lead, to which it is held by a brass frame, and can be used without touching with the hand while taking the sample. Further, all the apparatus used for testing and analysing tea, coffee, chicory, milk, alcohol, &c., is displayed. In a word, the visitor can see the applications of chemistry and bacteriology to the preservation of water- and food-supplies.

The next room contains the exhibits of the municipal veterinary department with very fine wax models of diseased meat, an exhibit which cannot fail to alarm a good many people and which prompted a visitor to exclaim somewhat appropriately, "Almost thou persuadest me to become a vegetarian." Perhaps, also, as a warning to the frequenters of cheap restaurants who have a weakness for *civet de lapin*, there are side by side the skeletons of a rabbit and a cat. With the exception of the heads the likeness between the two suggests how easy it would be to substitute the one for the other. Another department deals with the vegetable supply of Paris and there are maps showing from what parts of the country the various vegetables are obtained, together with pictures of the mushrooms that are edible and those that are poisonous. This exhibit includes the methods for detecting the effects of poisonous alimentary substances. Here is shown the apparatus devised by Professor Marey to record cardiac movements and a pump where a vacuum is produced by a fall of mercury, which is used to extract gases from the blood. The adjoining room or division is allotted to the demography of Paris where the growth of the population may be studied; and by its side there is a very large division containing every sort of information, plans and drawings concerning the domains of the town, its parks and gardens, its district town halls, the lands which it has bought in the provinces for asylums, convalescent homes, &c.

The next department, though most serious and technical, is so arranged that it does not fail to attract the general public and serves as a useful object lesson. It deals with the hospitals which, with but a few exceptions, are all under the management of the municipality. Here we find a little scenic effect. It consists of an old-fashioned four-poster bed, such as was employed at the old Hôtel Dieu a hundred years ago, and in which no less than four patients had to sleep. These patients are represented by life-sized lay figures. Three are in bed, one with his head at the bottom of the bed and his feet up by the faces of the other two patients. The fourth patient is sitting at the foot of the bed, so that the visitors may see the style of clothes that used to be provided in the hospitals. Indeed, these clothes are about the only satisfactory thing shown. By way of warming and ventilating there is a huge earthenware and portable receptacle that looks like an urn. Inside this some sort of smokeless fuel, presumably charcoal, used to be burnt, and it was brought close to the bed of the patients, thus helping still further to poison the atmosphere. The bed, bed-table, chairs, &c., are of wood. Immediately opposite there is a modern iron hospital bed and aseptic furniture such as is now used in the hospitals. In no case is wood employed, but only enamelled iron or hardware. Then there are the spittoons with a cone-shaped inner pan dipping into water which contains in solution some antiseptic. There is also a cylinder which can hold 14 spittoons. Below by means of a gas-burner water is warmed. There is a safety valve on one side, a thermometer on the other, and the steam generated disinfects the contents. These are now used in nearly all the hospitals though but a short time ago they were employed only in cases of phthisis. In another corner there are samples of the wheat, flour, &c., employed at the municipal bakery where the bread for all the hospitals is made. Next to this is a compartment which is fitted up more like a small drawing-room. This contains exhibits from the archives of the Public Assistance, a term which comprises poor relief, hospitals, and asylums. On the walls are several oil-paintings and these are the portraits of some of the best-known philanthropical benefactors. Then there are a number of documents, some parchment manuscripts illustrating former systems of poor relief, and a very fine illuminated mass book used in the hospital chapels. Round this little drawing-room there is all that relates to the care of infants and little children, notably those who are abandoned by their parents. There are models of hospitals for children, maternity hospitals, and specimen baby incubators. The latter are more useful as historical records, for they are very inferior to the more modern and improved types. There is also a glass partition that can be built up round a cot, so as to isolate the patient from the rest of the ward, and yet the patient remains visible from the ward. By the side of the kits provided for abandoned children there is a collection of strange tokens left with the children so that they may be ultimately recognised and reclaimed. Each child must wear up to the age of eight years a bead necklace to which a small medal is attached bearing a number. This number corresponds with the entry made in the book that records all that is known about the child. In frames there are diagrams and statistics setting forth, for instance, that while the number of children receiving public assistance in 1848 amounted to 13,000, 50 years later this help was extended to 28,000 children. Then come tables of the average number of children abandoned at the Hospice des Enfants Trouvés in periods of five years. The highest figure was 6800 and this dates back as far as the years 1770–74. In spite of the great increase of population there were only 4700 children thus abandoned from 1893 to 1898. During this century the maximum of abandoned children was 5803 in 1831, and the minimum was 2260 in 1876. Interspersed in different rooms are large glass cases containing elegant and elaborate costumes for ladies and other articles of clothing, embroidery, &c., all made by these abandoned children or other inmates of municipal asylums. There are likewise plans and drawings of various sanatoria, notably that of Hendaye for "scrofulous" children, and a very interesting and large album containing drawings and x ray photographs showing the results attained at Berck-sur-Mer in the treatment of Pott's disease. These were collected by Dr. V. Ménard, the chief surgeon in charge of this great establishment, where there are 710 beds for children needing sea air and sea bathing.

The next compartment is devoted to the meteorological work done by the city and in the centre there is a plan of Paris with a large number of pins so placed as to indicate

the whereabouts of the meteorological stations established in the capital. Attached to this service there is a bacteriological department which systematically and periodically tests and records the amount of microbes found in the atmosphere of the town. At the same time the air is analysed for ozone and for carbonic acid and the apparatus used is shown. Indeed, it is working in this section with the result that while no ozone has been found there is often an excess of carbonic acid. On the walls there are diagrams that represent an immense amount of labour. One gives per season, another per month, the meteorological variations recorded during the last 100 years. Below in the same columns are the variations in the prevailing diseases. Naturally this latter phase of the work is more ample and better classified during the latter part of the century. Still, such information as is available so as to establish the relationship between climate and disease is there, and all on the one chart. The next compartment might be called the municipal business department. It represents the money-realising services controlled by the municipality, such as the public markets, the omnibus lines, the Bercy wine depôt, the cemeteries, the museums, historical monuments, and the like. After that we come to the inspection of the habitation and its sanitary control. Here are models of the disinfecting stations which show how carefully the infected side is separated from the other side and how the attendants purify their uniforms, change all their clothes, and take a douche before they are allowed to go from one side to the other and mix with the general population. Dummy figures represent the attendants in their uniforms and also that worn by the nurses who help to remove the fever cases to the isolation hospitals. On the walls there are diagrams showing the prevalence of various contagious and infectious diseases in different parts of the town and also the quarters where it is necessary to disinfect most frequently. Finally, there are specimens of different clothing materials before and after disinfection. This is an important room for English visitors inasmuch as the French were much behind the English in practising disinfection, but now that it has become the custom their methods and their precautions are more minute and perfect than is usually the case in England. There is consequently a good deal to be learnt here. The next compartment indicates what has been done in organising relief by means of work—that is, in places where, under certain conditions, some sort of work is given and relief is granted when the task has been accomplished. This is a new and interesting institution founded so as to prevent the pauperisation of the destitute. This brings the visitor to the end of the right-hand side of the oblong pavilion of the City of Paris. There still remain the centre, the other side, and the galleries above. The questions of road surveying, drainage, sewage farms, water, gas, electric light, pneumatic motive power, domestic drainage, police, technical and other schools, primary education, &c., have still to be dealt with. Thus it will be seen what large and important exhibits are comprised in this one pavilion, and when from its balconies the visitor looks out on the miles and miles of Exhibition ground, thickly studded with other such pavilions, palaces, and enormous buildings, and thinks that they all contain objects of beauty and of interest, it does not seem like an exhibition but an entire world that is stretched out before him.

Paris, June 10th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Ravages of Famine and Cholera.—The Decline of Plague.—More Plague Rules.

THE enormous area of the famine and the terrible ravages of cholera have put all interest in the plague quite in the background. Although the total numbers under famine relief have not increased much during the past week, nothing could surpass the heartrending accounts of distress which are arriving at Simla from official and non-official sources. In some of the famine districts the mortality from cholera is appalling. In some places the natives refuse all outside assistance and they believe cholera to be a demon who is to be avoided by means of exorcisms and *poojahs* (prayers). At Bhagalpore the medical men tried to purify the wells, but there was such a row about it that they had to desist. As has been repeatedly recorded before, where cholera and plague are concerned ignorance and fear render the natives heartless In some places when a member of the family is attacked by the disease he or she is shut up in the house with a pitcher of water and left to die, while the rest—it may be parents, sister, wife, or husband—run away to avoid the infection. They may return to drag the corpse out of the hut and leave it in the open field to be food for the pariah dogs or the carrion birds. Help or sympathy is utterly wanting. In other places, again, groups may be seen lying beneath the trees, some dead and many dying. No attempt is made to remove the dead. The people have simply sat down there to die and they wait for death.

In view of this widespread and terrible distress it is satisfactory to find that plague is decreasing. The plague mortality throughout India last week was only 1214, as compared with the 1566 deaths which occurred the week before. Calcutta reported 170 deaths; Bombay city 342 deaths; Karachi 139 deaths; and Aden 59 deaths. With the satisfactory decline of plague it is astonishing to hear that the following addition has been made to the plague regulations in Bengal: "In any case in which the subdivisional magistrate or health officer thinks fit he is authorised to isolate the village or part of the village in which a case of plague is believed to have occurred by cordons, patrols, or in such other manner as he may think expedient. ..... No inmate of such village or part of a village shall leave the same or hold any communication with any other persons, and no other persons shall enter the same," &c. When it is known that the present Lieutenant-Governor avoids anything like compulsion in enforcing any of the existing regulations it will be obvious that this will be, as many other rules are, practically a dead letter. The Mahomedans in Benares met on May 11th and resolved to memorialise the Government against the plague rules to be introduced in the city. They have just discovered that they are contrary to the words of the Prophet. It is at least curious that this has not been noticed before. If it has been, however, I have not heard anything about it.

May 17th.

PLAGUE IN AUSTRALIA.

(FROM A SPECIAL CORRESPONDENT.)

THE returns of plague in Sydney for the week ending April 28th are as follows: Remaining at the beginning of the week, 70; admitted, 27; died, seven; remaining at the end of the week, 76. The total cases are now 156 and the total deaths are 53; the number discharged recovered is 27. Total "contacts" isolated, 924; "contacts" remaining, 260; cases among "contacts," five.

There is little of interest to record beyond the figures given above, only the number of cases has again approached the highest experienced in any preceding week. The rat-killing crusade hardly flourishes, and, indeed, the prevention of plague, in so far as it depends on destruction of rats, begins to appear impossible. It has been proposed that the ancient sport of ratting should be revived; it is a more hopeful suggestion than many others. In the meantime the capitation fee has been raised to 6*d*. Tubes containing cultures of some bacterium said to be capable of causing an infectious disease among rats have just been received from the Pasteur Institute; it was sent for on the independent testimony of an observer who, after watching its effects, felt sure that such an epidemic had been so caused. It is believed to be Danysz's microbe, but unfortunately has been forwarded accompanied only by those circulars which have been printed for information of the laity. However, it will not take very long to find out its characters and whether it is (as alleged) harmless to domestic animals, &c. The bacillus typhi murium certainly has not in this country the powers ascribed to it and, on the other hand, is fatal to many small birds at all events. It kills only the rats which eat food infected with it; very soon the whole colony becomes frightened and decamps, but no spreading illness is set up by it. This was ascertained in the laboratories of the department more than two years ago with the approach of plague in mind and has been checked by repeated experiments in the

field conducted under circumstances very favourable to observation. In all probability the speaker at the Berlin Conference on plague who suggested that rats especially disliked sulphurous acid because certain factories where water containing this body was constantly present were free from them, was right in his inference. This has long been known here and the practical use made of the knowledge during several years past has been the following. In fumigating ships for the purpose of destroying rats the quarantine staff are accustomed to burn quite small quantities of sulphur in the upper parts for the purpose of driving the rats into the holds and bilges. Retreat being then prevented they are very easily killed by burning more sulphur in the proportion of about three pounds per 1000 cubic feet. Unfortunately, sulphur damages many kinds of cargo, such as sugar, coffee, tea, &c. Still, those who suggest the substitution of carbon dioxide little understand the difficulties or the uses of sulphur. In attempting to prevent the introduction of plague it is absolutely essential that an island should be available on which cargoes might be landed for destruction of rats in them and while the nearly empty holds are fumigated. For obvious reasons cargo could not safely be landed from suspected ships on the mainland; and, indeed, the island should be a small one. But, as regards infected cities, if the plague does not itself kill off the rats how can any other communicable disease be expected to do it? The approach from France of a present of Yersin's serum, heralded with much circumstance, was anxiously regarded. The parcel has now come to hand and has been obligingly presented by the Consul-General, through the hands of the representative of the Pasteur Institute at Sydney. It consists of 120 cubic centimetres of serum and the equivalent of 10 cubic centimetres in dry form. These are very interesting exhibits and now occupy a place of honour on the shelves of the laboratory museum. The cleansing of portions of the city proceeds apace. A good enough thing in itself, it has no effect on the progress of the epidemic. Those who are of opinion that the virus can become localised in the soil will doubtless give it greater value than does the present writer. In other respects it is good exactly as far as it has gone. It is an attempt to repair in a hurry the effects of long neglect, and unless there is reform in the attitude of local authorities towards the health laws and the organisation of which the foundations have been laid by the department, in a few weeks the state of affairs must become as bad as it was before the cleansing. There are signs of an awakening, however. To provide machinery and to see it utterly neglected—to find the central health authority regarded as a local authority and expected to do the work of local authorities in every part of this extensive country—has been a disappointing and even an enraging situation. But epidemics are the sanitarian's opportunity and this one will yield its harvest in due time no doubt.

April 29th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Annual Report of the Medical Officer of Health of Liverpool for 1899.

THE report on the health of the city of Liverpool during the year 1899 by Dr. E. W. Hope, the medical officer of health, is an elaborate octavo volume of 234 pages. It is illustrated with a large map of the city and a diagram showing the birth-rate and death-rate in each of the districts of the city during 1899, together with the number of deaths of infants under one year out of every 1000 born and the estimated population per acre, excluding docks, quays, &c. The figures representing these four rates are printed in different colours, whereby comparisons of the corresponding rates in the 11 districts can be readily made. At the foot of this diagram is shown the birth-rate of the whole city during 1899, which was 33·6 per 1000 of the inhabitants, and the death-rate, which was 24·3 per 1000. The area of the city comprises 20½ square miles with an estimated population of 668,645 persons. The death-rate varied widely in different districts; the lowest death rate was in the Sefton Park district, where it was 10·1 per 1000. The highest was in the Exchange district, where it was 38·7 per 1000. An exceptionally large proportion of deaths occurred in workhouses and hospitals. The death-rate was higher by 0·9 per 1000 than in the preceding year, a fact attributed mainly to the prevalence of influenza which accounted for 203 deaths; but influenza was also associated with a large number of cases of fatal illness involving chiefly the respiratory system. A regrettable feature of the report was the increase in the number of deaths from excessive drinking. Deaths from measles and whooping-cough amongst children were especially deplored and caused 321 deaths and 314 deaths respectively. Dr. Hope again drew attention to the limitation of hospital accommodation; no provision had yet been made for measles and whooping-cough, whilst that for diphtheria was wholly inadequate. An interesting feature of the report was the increasing demand for accommodation in the city infectious hospitals. The present number of beds available for the various forms of infectious sickness is 480. Of these 37 are apportioned to small-pox cases, 20 to typhus fever, 75 to typhoid fever, 288 to scarlet fever, 30 to diphtheria, whilst 30 beds had to be kept for isolation purposes. Plans had been approved by the Local Government Board for the erection of small-pox wards for the accommodation of 44 patients at Fazakerley. Dr. Hope showed that at the lowest computation, based upon a wide experience and embodied in the recommendations of the Local Government Board, Liverpool requires a minimum of 650 beds for ordinary infectious sickness and 100 beds for small-pox. Possibly the recent outbreak of small-pox at the Liverpool Workhouse, which is now happily subsiding, may impress the Health Committee with the necessity for an increase in the number of beds for that disease. In a large seaport like Liverpool, with its extensive immigrant population, the dangers of infection from foreign ports cannot be over-estimated. There has been recorded in THE LANCET of May 26th and June 2nd the importation of a case of small-pox at Queenborough from Russia which found its way to Stalybridge, leading to deplorable results. It is to be hoped that a better supervision is exercised in Liverpool over ships arriving from the Continent; at the same time it would be always possible for an individual in the incubative stage of small-pox to pass muster even at that port, hence the necessity for an ample provision of beds in case of an outbreak of the disease in Liverpool. The steady decline in every form of tuberculosis is a satisfactory proof of the progress of sanitation in Liverpool. The report emphasised the fact that not only had every form of the disease diminished but at every age-period there had been a marked decline in the mortality from this cause; especially had this been the case in the earlier years of life, which was of the first importance. There had been a great increase in the number of references to and from the school board authorities chiefly relating to children who had come from infected houses and who were attending school. Special and systematic visits were made to courts and alleys with the object of ensuring the cleanliness of the domestic offices and the surfaces of the courts. Another satisfactory feature was the diminution in the number of courts and alleys owing to the demolition of low-class property for the extension of business premises or to the removal of insanitary property by the Insanitary Property and Artizans' Dwellings Committee. During the last nine years 733 courts had been demolished. An unsatisfactory feature of the report was the continuance of smoke nuisances to a very serious extent in spite of the infliction of heavy fines. The onerous and responsible work connected with the ambulance and disinfecting departments is fully described in the report and reflects much credit upon the respective staffs. The growing practice of the use of preservatives in the food-supply had been a matter of grave concern to the health authorities. Some of the preservatives under certain conditions had a poisonous effect. The total number of samples taken for chemical analysis was 1522, and the total number taken for bacteriological analysis reached 505. The work of the bacteriologist comprised (1) the examination of foodstuffs of various kinds; (2) regular examinations of water supplied to the city; (3) examinations into suspected cases of rabies, anthrax, glanders, &c.; (4) examinations for diagnostic purposes in suspected cases of diphtheria, typhoid fever, tuberculous sputa, &c.; and (5) special investigations, including the condition of the artificial foods supplied to infants giving rise to summer diarrhœa. The report also deals with the milk-supply to the city much on the same lines as last year, but pointing out that the Health Committee are seeking powers to still further safeguard the importation of milk into the city. The difficulties in the

way of re-housing persons displaced by the demolition of insanitary property, to which reference has been made in a former issue of THE LANCET, are increasing owing to the paucity of empty houses in the vicinity. Allusion is made in the report to the gratifying results which had accrued from the provision of public baths and wash-houses, which had been largely used by the poor of the city. For the purpose of carrying out the requirements of the various sanitary Acts of Parliament and the orders, by-laws, and regulations made thereunder, the staff of the medical officer of health's department consisted of 121 persons, comprising 96 inspectors and superintendents, 21 permanent clerical officials, three notice servers, and one temporary assistant. In every case officers are selected for these positions whose previous training and occupations had been such as to fit them for the special duties which they are called upon to discharge. Some are required to hold the certificate of the Sanitary Institute of Great Britain or a certificate equivalent thereto, others are required to possess marine engineers' first-class certificates, whilst the superintendent ambulance inspector must possess a sanitary certificate and also the certificate of the St. John Ambulance Association. The inspectors of meat and animals are required to be butchers by trade and those of fish and fruit must be fishmongers by trade. There are many other special points in the report which want of space prevents me from enumerating.

June 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Aberdeen University Sports.

THE ninth amateur meeting of the Aberdeen University Athletic Association was successfully held on June 7th and 8th at the University Recreation Ground, King's College. At the conclusion of the contests the Aberdeen team for the inter-University sports was selected.

Aberdeen Volunteer Medical Staff Corps.

The annual inspection of this corps took place in the grounds of the Grammar School on June 9th. There was a capital turn-out, 128 officers and men being on parade. The inspecting officer, Colonel J. P. Rooney, R.A.M.C., principal medical officer for the Scottish district, expressed himself as being exceedingly pleased with the corps.

Bequests to Aberdeen Hospitals.

By the death of Mrs. Macdonald of Kepplestone four hospitals will benefit to the extent of £1400 in all, of which £1000 will go to the Royal Infirmary. There is also a legacy of £100 to the Aberdeen District Nursing Association. All the legacies are free of duty.

June 12th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Apothecaries' Hall of Dublin.

MUCH satisfaction was felt in Dublin at the decision of the General Medical Council with reference to the examinations of the Apothecaries' Hall as reported in the proceedings of the Council contained in THE LANCET. Reports were received from the inspector, Dr. G. A. Gibson, stating that he had inspected the last three examinations, held in October, January, and April last, and that they were satisfactory in every respect.

The Gas-supply of Dublin.

Ever since the attention of the Dublin public was drawn to the dangers attending the addition of carburetted water-gas to the ordinary illuminating gas supplied to the citizens and to the necessity of precaution with reference to the fittings in houses in order to prevent leakage of a mixture now become more poisonous than heretofore, much anxiety has shown itself. It will be remembered that the above warning was conveyed in a letter addressed by Professor Emerson Reynolds of Trinity College to the Dublin papers some months ago. At a monthly meeting of the Dublin Corporation held on June 11th the matter was under discussion and it appeared that the Alliance and Dublin Consumers Gas Company has recently laid down plant by which they would be enabled to produce 4,000,000 cubic feet of water-gas per day, thus exceeding their present supply by 1,000,000 cubic feet. A proposal made by Alderman Meade was ultimately agreed to—viz., that the question should be referred to the special Gas Committee in order that full information as to the properties of the gas and the danger to life of admixtures of it might be obtained from experts.

The Typhoid Fever Outbreak at Belfast.

The medical superintendent officer of health of Belfast reports that the death-rate for the week ended June 2nd was 19·5 per 1000 from all sources, and 2·8 from the principal zymotic diseases. In the corresponding period of 1899 the death-rate from all causes was 23·1 and from zymotic diseases 1·9 (including only two from typhoid fever). For the week ending June 2nd 57 cases of typhoid fever were notified in Belfast. He also reported that the water-supply of the city was anything but satisfactory, and he advised the boiling of all water to be used for drinking or culinary purposes.

Burning of Newry Workhouse.

Newry workhouse was burned down on the night of June 7th. The local and military fire brigades were at hand, but owing to the want of water they were quite helpless. The infirm patients were carried to the fever hospital which is close to the workhouse, and during the course of removal one of the infirm patients expired and many others were much weakened from shock. It seems that, though repeated warnings were made as to the danger in case of fire and in spite of the master's request for fire appliances the guardians have been wrangling for a year over the question of introducing a water-supply from the town. Naturally great indignation is felt at their remissness. It is said that the fire was caused by the upsetting of a lamp, no gas being in the building. Fortunately there were only 200 inmates and as the fever hospital was empty no difficulty was experienced in providing for their accommodation. It is stated that the damage done will amount to close on £5000, but the place is insured. At a meeting of the Newry guardians on June 9th a sub-committee was appointed to consult with the architect in reference to the rebuilding of the place.

The Royal University Graduates' Association.

The secretaries of this association, which was formed last year (when Mr. Balfour's scheme was under discussion) to oppose the destruction of the Royal University of Ireland and the establishment of universities under sectarian control, have issued a circular to the graduates, who number upwards of 5000, urging them to become members of Convocation, so that no graduate shall be elected a member of the Senate who was in favour of sectarian universities. In this circular a very fair and judicial expression is given of the views of the Graduates' Association on the question of university education. They hold that continuity is essential to the success of a university, and they believe that improvement in Irish university education should be looked for not through destructive legislation, but through reforms in the internal organisation of the university and its associated colleges. They think that if the Royal University was re-organised—and an example in this direction is afforded by the London University—with the view of honestly promoting university education and not sectarian interests, the problem of Irish university education would be solved.

The Belfast Asylum and the Infectious Diseases Hospital.

At the usual monthly meeting of the Belfast Asylum governors held on June 11th, the following resolution, of which notice had been given, was upon discussion passed by 6 to 4 votes :—

That his Excellency the Lord-Lieutenant of Ireland be requested to take such steps as he may consider proper to prevent the erection of an infectious diseases hospital on any portion of the lands of Purdysburn which have been acquired for lunatic asylum purposes.

A very stormy discussion took place at the committee meeting in reference to a verdict of a coroner's jury on a female patient who died in the asylum from phthisis.

(FROM OUR OWN CORRESPONDENT.)

The Illegal Practice of Medicine by Masseurs and Magnetisers.

THIS question, which is a matter of the highest interest as regards the rights of the medical profession, remains in abeyance, the courts in different departments having given different judgments in absolutely similar cases. In the department of the Sarthe, for instance, illegal practice of medicine flourishes unchecked, thanks to the indulgence afforded to masseurs and magnetisers by the courts, an indulgence which is made manifest by various judgments which by the medical profession are considered to be simply scandalous. The Court of Cassation has just decided to study the question, and although it has not yet given any decision the report of the counsel to whom was entrusted the inquiry is so favourable to the magnetisers that there is great fear of the court giving a decision in accordance with this disastrous opinion. It is true that the duty of the Court of Cassation is to interpret the formal text of the law and not to reform it even when it is manifestly bad. On this view it must be remembered that the law of 1892 which defined the illegal practice of medicine did not specially mention magnetisers. The Government Commissioner who was charged with seeing the Bill through the Chamber was Dr. Brouardel, now Dean of the Faculty of Medicine. In the original draft of the Bill magnetisers were expressly mentioned. The Chamber, however, was not at all prepared to look upon the Bill with favour in view of the opinions of many country electors, among whom bone-setters and quacks of all kinds enjoy great popularity and afford valuable help to the deputies at election times. Dr. Brouardel thought for the moment that the whole Bill would be lost, so he considered it better to make some concessions and the magnetisers were struck out. If the Court of Cassation adheres to the strict letter of the law and declares that magnetisers are not illegal practitioners the door to similar illegal practice will remain open unless some special law is passed to prevent it, which is extremely unlikely. Magnetisers are getting more and more numerous and have founded a school of magnetiser-masseurs which is a regular breeding ground for quacks and which solemnly issues diplomas by the aid of which the recipients make a good thing out of public credulity. They hold regular consultations, put a stop to treatment already recommended, and, not content with using magnetic passes, prescribe magnetised water which has been magnetised by themselves. It is, at first sight, astonishing to see masseurs joining with magnetisers, for they have nothing in common with these latter except in doing illegal practice by attributing medicinal virtues to movements. But masseurs have been formally taken cognisance of by the law from the point of view of illegal practice. Often, too, they have been sentenced by the courts; for instance, only recently the Court of Versailles sentenced a masseur who had treated two fractures and a dislocation, although the prisoner had been acquitted for a like offence by the Court of Mantes, which enunciated the remarkable opinion that the practice of massage was under no restriction whatever. The Court of Versailles, however, rejected this theory, quoting the terms of the law of 1892, which defines illegal practice as the continuous treatment (*diriger d'une façon suivie le traitement*) of surgical diseases or affections by anyone who has not a diploma except in such cases as when urgency is definitely proved. The court further added that the word "treatment" means any act or advice tending to the cure or alleviation of an illness or state of illness and that it must not be arbitrarily confined to a prescription for drugs or to the performance of surgical operations properly so-called. Masseurs, then, whose status is clearly defined have an incentive to associate themselves with magnetisers whose legal status is still indefinite. On the other hand, magnetisers, who are rightly considered by a great part of the public as quacks, have every incentive to pretend that their practices are similar to massage, of which the public hear the benefits lauded by medical men themselves. Here, then, is the explanation of this unnatural combination which at first sight seems inexplicable.

The Carriage of Small-pox by Flies.

At the meeting of the Academy of Medicine held on June 5th M. Hervieux, who has made a special study of the vaccination question, read a report of some observations made by M. Laforgue at Tamorna-Djedida in the province of Constantine. During an epidemic of small-pox at that place M. Laforgue ascertained that the parents of children who were attacked by small-pox all lived in the south-west of the village and that the northern part remained unaffected. He explained this fact as due to the direction of the prevailing winds which blow, especially during March and April. He also noticed that flies and gnats which become very numerous about this time are distributed with the wind. As these insects are known to play an important part in the dissemination of granular conjunctivitis M. Laforgue is of opinion that they act in the same way as regards small-pox, acting as carriers of the specific virus.

Obituary.

Dr. Cadet of Cassicourt died on June 10th at the age of 72 years. He was honorary physician to the Trousseau Hospital and a member and formerly annual secretary of the Legion of Honour. He had a great reputation for his knowledge of infantile pathology and left a large number of works upon that subject, especially the "Treatise upon the Diseases of Children." M. Masson, the well-known medical publisher, has just died. He succeeded his father, Victor Masson, as the head of the most important medical publishing house in France, and the number of medical and scientific journals published by the house amounted to 50. He was librarian of the Academy of Medicine, treasurer of the Association of French Medical Men, President of the Paris Chamber of Commerce, and Commander of the Legion of Honour. He was a man of the highest integrity and had no enemies.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Hetol, a Remedy for Tuberculosis.

HETOL, or cinnamate of sodium, has been recommended by Professor Landerer of Stuttgart as a specific against tuberculosis and has been tried by Professor Ewald, whose results as described in a communication made to the *Berliner Klinische Wochenschrift* were less positive than those obtained by the originator of the method. The mode of administration was by injection into the median vein, the amount commencing with one milligramme and rising to 15 milligrammes. The injections were given to 25 patients, of whom one had laryngeal tuberculosis and the others had pulmonary tuberculosis, and all of them were in a stage of the disease in which successful treatment was still possible. The influence of the injections was shown by small hæmorrhages in the sputa; somewhat abundant hæmoptysis being observed only once. Another symptom was a sensation of drowsiness felt by the patients after the injections. The bacilli were not influenced by hetol nor was any effect observed on the perspiration or the temperature. With regard to the influence of the treatment on the general condition of the patients, Professor Ewald stated that in four cases complete success was obtained; in five cases there was an improvement; in six cases the progress of the disease was stopped; whilst in ten instances there was a rapid deterioration. One patient died after having been for 316 days in the hospital and after having had 70 injections. The post-mortem examination showed that the pulmonary tuberculosis had healed, but that there was a well-marked fatty degeneration of the heart which was the cause of death. In 14 cases an increase of weight was observed, but this was the rule with many patients of the poorer class who improved at once after admission to hospital on account of the food and the hygienic conditions being better than in their own homes. As to the patients in whom the disease continued its progress the report stated that seven out of 10 died. The prognosis of these cases was not very bad at the outset, as patients of this kind had not been chosen for the treatment. Professor Ewald concluded that success was obtained in only 8 per cent. of the cases. The results met with in the Augusta Hospital were therefore not in accordance with the experience of Professor Landerer. The method, being harmless, might be tried on a larger scale; but the statistics appeared to be not much better than those furnished by well-conducted sanatoria. In fact, many of the recoveries from phthisis were not due to any specific treatment but to the vital power of the organism when it was assisted by hygienic measures.

The German Ambulances with the Boers.

A second letter from Dr. Hildebrandt, one of the German medical officers to the Red Cross ambulances with the Boer army, has been published in the *Münchener Medicinische Wochenschrift*. In this communication, which was dated from Pretoria on April 7th, he referred to the occurrences after the capture of Jacobsdal by the British troops, a turn of events with which he was well satisfied, not only because the ambulance had then plenty of work, but also because the British authorities were much more agreeable to deal with than the Boers. The members of the ambulance had to pay for food and, in fact, for everything they wanted, and they were hindered in every way when they made requests for the sake of the wounded. The British authorities, on the other hand, met their wishes as much as possible. One of the surgeons and two attendants caught enteric fever. After the battles near Jacobsdal the ambulance had to provide for about 120 wounded soldiers, the majority being serious cases, but it fortunately happened that the wounds inflicted by modern rifle-bullets required operation only very seldom; wounds of the brain, however, where suppuration often ensued had to be operated on in many instances. The majority of intestinal wounds healed by conservative treatment. The ambulance received not only Boers but also British officers and men.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Bacillus of Hospital Gangrene.

AT a recent meeting of the Vienna Society of Physicians there was an interesting discussion on the Etiology of Hospital Gangrene. It was introduced by a paper communicated by Dr. Matzenauer, an assistant in Professor Neumann's clinic for syphilis and dermatology, who stated that he had observed 22 cases of hospital gangrene situated on the penis and prepuce. On microscopical examination he found that the ulcers showed an inflammation causing early coagulation-necrosis of the tissues. In all these cases, especially at the junction of the inflamed and the necrotic tissues, there was a bacillus which could be stained by Weigert's method and seemed to be anaerobic. Cultures of the bacillus could be obtained only with difficulty and inoculation experiments did not give any result. Dr. Matzenauer pointed out that these gangrenous ulcers did not produce any enlargement of the inguinal glands. Some of the speakers were of opinion that the cases ought not to be called hospital gangrene, a disease which had hardly been seen for the last 30 years. It was, therefore, improbable that no less than 22 cases of that extinct disease should have occurred in one ward of the clinic in the course of the last three years, and the general opinion of the meeting was that the cases described by Dr. Matzenauer were merely phagedenic chancres and ulcers. On the other hand, it was admitted that the ulcers described by him showed the clinical signs attributed to hospital gangrene by various authors, and that as the bacillus discovered by him was found in all the cases it might be the cause of the disease, even though the experiments made on animals gave no result.

Peculiar Corpuscles in the Blood of Syphilitic Persons.

Dr. Lostorfer of Vienna has published a preliminary communication in which he states that some days after the appearance of a chancre, but before the coming out of the syphilitic eruption, small round corpuscles of the size of the blood-granules, having a peculiar lustre, are to be found in the blood of the patients. These corpuscles aggregate after some hours in groups of from two to 20, forming oblong bodies. After three days they begin to disappear, especially when mercurial treatment has been commenced, and after 20 or 25 inunctions they can no longer be found. Dr. Lostorfer could not find these corpuscles either in the blood of healthy persons or in that of patients suffering from other diseases than syphilis. Professor Paltauf confirmed this statement of Dr. Lostorfer; he said that these corpuscles were not stained with the ordinary staining solutions; they became more visible on the addition of acetic acid, and he believed that they were products secreted by tissues or coagula, but he could not state if they had a specific character. More than 20 years ago Dr. Lostorfer caused an animated controversy among the leading histologists by his alleged discovery of specific corpuscles in the blood of syphilitic patients, but on the present occasion he did not mention whether his recently discovered corpuscles were similar to those found before

June 11th.

Obituary.

GEORGE EDWARD WILLIAMSON, F.R.C.S. ENG.

DEATH has been very busy in the ranks of the medical profession at Newcastle-upon-Tyne during the last 12 months, seven well-known medical men having died. The latest of these is Mr. G. E. Williamson who succumbed to an acute attack of pleuro-pneumonia on Wednesday, June 6th. On the previous Thursday Mr. Williamson did his work in the Royal Infirmary, apparently in his usual health. Before leaving the institution, however, he complained to his house surgeon of not feeling well, and on arrival at his house in Eldon-square he had a rigor and retired to bed. Dr. D. Drummond saw him the same evening and found him to be suffering from an attack of pneumonia which ran a very acute course and terminated fatally on the sixth day. Throughout his illness he was most assiduously attended by his old friend Dr. Drummond and by Dr. J. D. Wardale, who for some years has acted as his assistant in the ophthalmic department of the Royal Infirmary.

Mr. Williamson was born at North Shields 48 years ago and received his medical education at the London Hospital, where he was a distinguished student and held several resident appointments. He also studied for a time in Paris. In 1874 he received the diploma of M.R.C.S. Eng. and in 1875 that of L.S.A.; in 1878 he was admitted F.R.C.S. Eng. He came to Newcastle to be house surgeon in the Royal Infirmary and was subsequently assistant to the late Mr. Heath, until in 1879 he commenced practice on his own account as an ophthalmic surgeon. He had already shown his inclination towards this branch of professional work while attending the Royal Ophthalmic Hospital, Moorfields, and he eventually made a reputation which led to his being appointed ophthalmic surgeon to the Royal Infirmary and lecturer in physiology in the University of Durham College of Medicine in Newcastle. On the death of Professor Arnison a few months ago Mr. Williamson became the colleague of Professor F. Page in the chair of surgery and was engaged up to the time of his death in conducting his operative surgery class.

He was till quite recently honorary secretary and treasurer of the North of England Branch of the British Medical Association and a representative of the branch on the General Council of the Association. At the meeting of the Association in Newcastle in 1893 he presided over the section of Ophthalmology, his address at the opening of the section being on the subjects of refraction testing and medical education in ophthalmology. Mr. Williamson was connected for 12 years as honorary surgeon with the Northern Counties Institution for the Deaf and Dumb and he took a very active interest in the Surgical Aid Society. The deceased was held in the highest esteem by his medical colleagues as well as by a wide circle of friends in the city, and much sympathy is felt for his widow and five young sons. The funeral took place on June 9th at St. Andrew's Cemetery, Moor Edge, in presence of a numerous assemblage.

THOMAS FITZ-PATRICK, M.D., M.A. DUB., M.D. CANTAB., M.R.C.P. LOND.

DR. THOMAS FITZ-PATRICK of 30, Sussex-gardens, Hyde Park, W., whose death is announced, was a distinguished graduate of Dublin University, obtaining his M.D. degree in 1862 and his M.A. in 1864. He was admitted M.D. of Cambridge in 1867 and M.R.C.P. Lond. in 1868. In 1856, the same year in which he was awarded the silver medal of the Pathological Society of Dublin for his work on "Chronic Diseases of the Liver," he indicated his future successes in his profession by passing, at a competitive examination, for the post of assistant surgeon in the service of the Honourable East India Company. His

health, however, soon broke down and after practising for some years in Ireland he settled to private practice in London. He married in 1865 Agnes Letitia, youngest daughter of the late William Robinson, LL.D., of Tottenham, Middlesex, of the Inner Temple, Barrister-at-law, J.P., and deputy-lieutenant of the county. He became a Fellow of the Royal Medical and Chirurgical Society and served as a member of its council in 1894–95; he was also a member of the Clinical Society of London. Dr. Fitz-Patrick was, however, far more than a talented physician. He was a *savant* in its highest sense and a linguist of high order, conversing in Italian, German, and French almost as fluently as in his own language, while his attainments as a classical scholar were far above the average. Moreover, he could read modern Greek with as much ease and pleasure as English. He possessed to a remarkable extent the faculty, so essential to members of the profession, of winning the confidence and attachment of his patients as well as the love and esteem of countless private friends. Unselfish almost to a fault, his thoughtfulness for everyone and his generosity and kindness to all who required help were proverbial, and it may truly be said of him that his right hand never knew what his left hand did. His two books, "An Autumn Cruise in the Ægean, or Notes of a Voyage in a Sailing Yacht," and "A Transatlantic Holiday," proved him the owner of a facile and graceful pen. He was a brilliant conversationalist and a *raconteur* with an absolutely wonderful memory for reciting either prose or poetry. In short he was a man of varied attainments, a steadfast and true friend, and a devoted husband.

JULIUS ALTHAUS, M.D. BERLIN, M.R.C.P. LOND.

THE death is announced of Dr. Julius Althaus in his sixty-eighth year. He was born at Detmold, in Germany, in 1833, where his father was a Lutheran minister. At the age of 17 years young Althaus entered the University of Bonn, intending to study classics, but before long he devoted himself to the subjects of medicine and natural philosophy. In the year 1851 he commenced to study medicine at the University of Gottingen, and thence went to Heidelberg and Berlin, at which last place he was selected by the great physiologist Müller to accompany him on a voyage of research to Sicily. Having taken the degree of M.D. at Berlin he went to Paris, Vienna, Prague, and London to perfect his studies. He finally settled in London, becoming a Member of the Royal College of Physicians in 1860. Having devoted himself mainly to the study of the nervous system and to electrical treatment, he was for some time assistant to the late Dr. R. B. Todd in King's College Hospital. In 1866 he founded the Hospital for Epilepsy and Paralysis in Regent's Park, where he acted as physician for 28 years and to which in 1894 he was unanimously elected consulting physician. He was a voluminous writer, chiefly of books upon electrical treatment and diseases of the nervous system, and his book upon "Failure of Brain Power" reached a fifth edition, the circulation being largely among laymen. Apart from purely professional knowledge he was a man of varied attainments and a good musician. He was a firm believer in the value of and necessity for a holiday, and last year while enjoying one in Switzerland met with an injury to his knee which was the beginning of his fatal illness. Gout supervened, followed by phlebitis and peritonitis, from which last complication he succumbed. His death is mourned by a large circle of patients and friends.

W. T. RADFORD, M.D. T.C.D.

ON May 19th there died at Sidmouth Dr. W. T. Radford at the patriarchal age of 89 years. He was the son of Peter Radford, a well-known physician in the West of England at the beginning of the present century. Dr. Radford was educated at Trinity College, Dublin, where he took the degree of M.D., and being blessed with private means he never practised his profession as a means of livelihood, but devoted himself to science and art. He was one of the earliest members of the Athenæum Club and travelled a great deal upon the continent, studying ecclesiastical architecture. He settled with his brother's family at Sidmount, near Sidmouth. Some 30 years ago it came to his knowledge that the poor, and especially lace-workers, were constantly imposed upon by itinerant vendors of spectacles, a fact which was often the cause of injury to their eyesight. He therefore gave out that he would supply any applicant whom he considered deserving with a pair of spectacles, and in addition he personally saw the applicants and tested their sight. He was a firm supporter of the local cottage hospital and dispensary, the former of which institutions was mainly founded by members of his family.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Heinrich Laudahn, Director of the Lindenburg Asylum, Cologne, at the age of 70 years.—Dr. Leopold Grossmann, the *doyen* of Hungarian ophthalmologists, at the age of 79 years.—Dr. Korsakoff, Professor of Mental Diseases in the University of Moscow, at the age of 48 years.—Dr. Benjamin F. Leonhard, Professor of Gynæcology and Children's Diseases in the Baltimore Medical College.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen have passed the First Professional Examination for the Diploma of Fellow:—

Joseph Ebenezer Adams, St. Thomas's Hospital; Robert Young Aitkin, M.D. Glasg., Glasgow University; Kenneth Anderson, Guy's Hospital; Charles Todd Andrew, Aberdeen University; Austin Lewis Badcock and Eric Bayley, Charing-cross Hospital; Edward Augustine Bell, King's College Hospital; Percy Stanley Blaker, M.R.C.S. Eng., L.R.C.P. Lond., Calcutta Medical College and University College, London; Harold Burrows, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's Hospital; John Beuzeville Byles, M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., Westminster Hospital; John Cameron, M.R.C.S. Eng., L.R.C.P. Lond., M.B., Ch.B. Edin., Edinburgh University; James Alane Coupland, Yorkshire College, Leeds; Maurice A. M. Fitzmaurice-Kelly, St. Mary's Hospital; William Robert Gibson, M.R.C.S. Eng., L.R.C.P. Lond., and John Dawson Hartley, M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's and King's College Hospitals; Douglas Gray, Charing-cross Hospital; Edward Erskine Henderson, M.B., B.C. Cantab., Cambridge University, Guy's, and King's College Hospitals; Joseph Tremayne Hicks, Guy's Hospital; Somerville Hastings, Gerald Stephen Hughes, and William Warwick James, L.D.S. Eng., Middlesex Hospital; Robert Jacques, University College, Liverpool, and King's College, London; John Charles Grant Ledingham, B.Sc. Aberd., Aberdeen University; William Archibald Logan, M.B., Ch.B. New Zeal., M.R.C.S. Eng., L.R.C.P. Lond., New Zealand University, Dunedin, and King's College, London; Harold Ashton Lyth, University College, London; James McClure, M.B., C.M. Glasg., M.R.C.S. Eng., L.R.C.P. Lond., Glasgow University; Arthur Ronald McLachlan, M.R.C.S. Eng., L.R.C.P. Lond., Guy's Hospital; Thomas Holmes Middleboro', M.D. Toronto, M.R.C.S Eng., L.R.C.P. Lond., Toronto University, Canada, and Middlesex Hospital; Harry Overy, Edinburgh and St. Andrews Universities; John George Pardoe, M.B., C.M. Aberd., M.R.C.S. Eng., L.R.C.P. Lond., Aberdeen University and King's College London; John Herbert Parsons, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., University College and Royal Infirmary, Bristol, and University College, London; Carrick Hey Robertson, and Robert Pugh Rowlands, M.R.C.S. Eng., L.R.C.P. Lond., Guy's Hospital; Percy Wm. George Sargent, M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., Cambridge University, and St. Thomas's Hospital; Arthur Reginald Schofield and Hugh Barnard Willoughby Smith, London Hospital; William Edward James Tuhoy, Guy's Hospital; Herbert George Tymms, M.B., B.S. Melb., M.R.C.S. Eng., L.R.C.P. Lond., Melbourne University, St. Bartholomew's Hospital, and King's College, London; Sidney James Wareham, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A. Lond., Charing-cross Hospital; Noel Everard Waterfield and Herbert Victor Wenham, St. Bartholomew's Hospital; John Harry Watson, M.R.C.S. Eng., and L.R.C.P. Lond., University College and Royal Infirmary, Liverpool, and King's College, London; Moses Thomas Williams, London Hospital; Bertram Shera Wills, M.R.C.S. Eng., L.R.C.P. Lond., St. Thomas's Hospital.

Of the 113 gentlemen who presented themselves for this examination, 44 passed and 69 were referred.

The following gentlemen having passed the necessary examinations and conformed to the by-laws and regulations, have been admitted Fellows of the College in the order of their seniority as Members:—

Thomas Richard Mulroney (Major I.M.S., Bengal), M.D. Malta, L.R.C.P. & S. Edin., Bombay and King's College, London, date of Membership, Jan. 19th, 1880; Frederic Victor Milward, M.B., B.C. Cantab., L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital, Member Feb. 7th, 1895; Hugh Mallinson Rigby, M.B., B.S. Lond., L.R.C.P. Lond., London Hospital, Member Feb. 7th, 1895; John Shields Fairbairn, M.B., B.Ch. Oxon., L.R.C.P. Lond., Oxford University and St. Thomas's Hospital, Member Nov. 14th, 1895; Louis Bathe Rawling, M.B., B.C. Cantab., L.R.C.P. Lond., St. Bartholomew's Hospital, Member August 4th, 1896; Stephen Frederick Lynch, L.R.C.P. Lond., King's College Hospital, Member Feb. 11th, 1897; Malcolm Goodworth Dyson, L.R.C.P. Lond., St. Bartholomew's Hospital,

Member May 13th, 1897; Donald John Armour, M.B. Toronto, M.R.C.P. Lond., M.C.P. & S. Ont., University of Toronto, Canada, and University College, London, Member July 8th, 1897; William Douglas Harmer, M.B., B.C. Cantab, L.R.C.P. Lond., St. Bartholomew's Hospital, Member August 2nd, 1898; Walter John Henry Hislop, M.B., C.M. Edin., L.R.C.P. Lond., St. Bartholomew's Hospital, Member August 2nd, 1898; Herbert Sherwell Clogg, M.B. Lond., L.R.C.P. Lond., Charing-cross Hospital, Member Nov. 10th, 1898; Lawrie Hugh McGavin, L.R.C.P. Lond., Guy's Hospital, Member Nov. 10th, 1898; Arthur Webb Jones, L.R.C.P. Lond., St. Thomas's Hospital, Member Feb. 9th, 1899; Thomas Holmes Middlebro', M.B. Toronto, L.R.C.P. Lond., University of Toronto, Canada, and King's College, London, Member Nov. 2nd, 1899; and John Percy Lockhart Mummery, L.R.C.P. Lond., St. George's Hospital, Member Nov. 2nd, 1899.

Of the 32 gentlemen who presented themselves for this examination 15 passed and 17 were referred.

UNIVERSITY OF CAMBRIDGE.—The following degrees were conferred at the Congregation on June 7th:—

Doctor of Medicine.—L. Falkener, M.A., King's; A. H. Thompson, M.A., Trinity; W. J. Harris, M.A., Christ's.

Bachelor of Medicine.—N. J. McCaskie, B.A., and E. A. Wilson, B.A., of Caius; J. E. Linnell, B.A., of Selwyn.

Bachelor of Medicine and Bachelor of Surgery.—J. G. Taylor, B.A., King's; W. P. S. Branson, B.A., Trinity; C. E. Marriott, B.A., Clare; E. Cox, B.A., and W. M. Willoughby, B.A., Caius; H. G. Cooper, B.A., Emmanuel.

Bachelor of Surgery.—L. Falkener, M.A., King's; T. S. Taylor, B.A., King's; W. L. Ascherson, non-collegiate.

The Raymond Horton-Smith Prize for the best M.D. thesis of the year has been awarded to Mr. Alan Baldrey Green, M.A., M.B., B.C., of Downing College. His subject was "Amyloid Disease."—Dr. G. H. F. Nuttall has been appointed University Lecturer in Bacteriology and Preventive Medicine.—The election to the Knightbridge Professorship of Moral Philosophy, vacant by the resignation of Dr. Sidgwick, will be held on June 30th.—Mr. G. F. C. Searle of Peterhouse has been appointed University Lecturer in Physics.—The Right Hon. A. J. Balfour, M.P., will deliver the inaugural lecture of the University extension summer courses on August 2nd.

THE MIDDLESEX HOSPITAL. — Miss Palmer Lovell has forwarded the sum of £315 to the treasurers of this hospital to endow a bed for the remainder of her life.

PRESENTATION TO A MEDICAL MAN. — On June 3rd, in the waiting-room of the Great Western Railway-station, Frome (Somerset), the members of the railway employés' ambulance class were presented by Mrs. Chill with badges and certificates of the St. John Ambulance Association. Mr. Edwin Albert Chill, M.D., C.M. Edin., was presented with a framed photographic group of the class as a mark of appreciation of his services as honorary instructor.

VACCINATION LAW.—At the last meeting of the Lampeter (Wales) Board of Guardians it was reported that the two youngest children of a medical practitioner in Lampeter were unvaccinated, the father having given certificates under his own signature of the unfitness of his children to be vaccinated on the ground that one was suffering from "anæmia" and the other from "neurasthenia." The question arose whether certificates given by a medical man in respect of his own children would be sufficient if the certifier were summoned for non-compliance with the vaccination law and the guardians had requested the medical practitioner to allow an independent medical man to examine the children, but this had not been permitted. The guardians eventually decided to consult the Local Government Board upon the matter.

FREEMASONRY.—*The Rahere Lodge, No. 2546.*—The installation meeting of the Rahere Lodge, No. 2546, was held in the Great Hall of St. Bartholomew's Hospital on Tuesday, June 12th. Bro. J. H. Drysdale, M.D., was elected a joining member. Bro. the Rev. Sir Borradaile Savory, Bart., and Bro. Cross were re-elected members of the standing committee, and Bro. A. W. Izard was elected a member of this committee. Bro. Reece, the W.M., installed his successor, Bro. Walter Gripper, P.P.G.D. Surrey, as W.M. for the ensuing year. A past-master's jewel was awarded to Bro. Reece, and Bro. Gripper, in the name of the Lodge, presented Bro. D'Arcy Power with the jewel of a P.G.D. in recognition of his services to the Lodge in the capacity of secretary and as a token of their appreciation on his appointment to the office of a Junior Grand Deacon. The report of the Audit Committee was received and adopted. The brethren and their guests to the number of 90 afterwards dined together at the Restaurant Frascati.

NEWPORT (MON.) WATERWORKS.—The total expenditure by the Newport Corporation on the Wentwood Waterworks up to the present has been £207,808.

THE NEW INFIRMARY, WARRINGTON. — This infirmary has been formally opened by Sir J. T. Hibbert, Chairman of the Lancashire County Council. It has been erected by the Warrington Board of Guardians at an outlay of £30,000 and will provide 184 beds.

THE BECKENHAM AND PENGE MEDICAL SOCIETY.—The fifth annual dinner of the Beckenham and Penge Medical Society took place on Thursday evening, May 31st, at Beckenham and was well attended by members and guests. Among the latter were Dr. J. G. Glover (Direct Representative on the General Medical Council), Dr. Handfield-Jones, and Mr. Arbuthnot Lane. Mr. Victor Horsley sent a message regretting his inability to be present. Dr. R. M. H. Randell, Vice-President of the Society, occupied the chair. Mr. Frank Sturges, in proposing the toast of "The General Medical Council," spoke of the work of the Council generally in terms of praise, and claimed for his society and for kindred associations the credit of having by their work impressed upon the Council a clearer idea of what was expected from them as the governing body and the mouthpiece of the profession. That the Council were now alive to their responsibility was shown by their energy and public spirit which in the last few years had become so increasingly apparent. Alluding to the Midwives Bill Mr. Sturges said that the Beckenham and Penge Medical Society were now of opinion that some legislation was necessary and even desirable, but they trusted to the Council to continue to use all their influence against any Bill which went further than simply to replace the present midwife, a danger to life and society, by a class of well-trained women of good character properly instructed as to where their duties began and ended. Referring to the proposed conciliation board Mr. Sturges expressed the opinion that in such a way the club difficulty could be overcome. He was proud of the action of his society on this question. Charity had nothing to do with it. The more important friendly societies were wealthy and powerful organisations, and that they should pay properly for medical attendance under proper regulations was simply a matter of business into which sentiment had no right to enter. In coupling the toast with the name of Dr. Glover Mr. Sturges said how completely they disapproved of the way in which the remnant of the Cannon-street meeting had treated their Direct Representative. They (the Beckenham and Penge Medical Society) had actively assisted in the promotion of that meeting because they disliked much in the present Midwives Bill and believed that the profession should speak out, but the methods of the promoters were distasteful to them and in future they should act by themselves. He trusted that the vote of sympathy and confidence unanimously carried at a large meeting of the society was some slight consolation to Dr. Glover. In his reply Dr. Glover thanked the society on behalf of the Council. He quite agreed as to the necessity for the restriction of the functions of the midwife as distinguished from the medical practitioner. He especially insisted that any legislation of the sort must, in the interest of the poor lying-in woman, stop the practice of unlicensed midwives, otherwise it would be quite valueless and should be resisted. He was glad to know that the proposal of a conciliation board had the approval of the society. The success or failure of the scheme rested very much with the British Medical Association. In conclusion, Dr. Glover thanked the society for their words of personal kindness and support. The Rev. Henry Arnott, F.R.C.S., rector of Beckenham, in proposing the toast of "The Beckenham and Penge Medical Society" spoke of the value of such societies in increasing professional knowledge and promoting fellow-feeling and a kindly spirit one to another, but he urged the society to follow the lines of the Royal Medical and Chirurgical Society and the Pathological Society of London, and to leave medico-political questions to be dealt with by the General Medical Council and the British Medical Association. Dr. Randell, in his reply for the society, maintained that it was part of their duty to take an active interest in all public questions vital to the profession, that knowledge was gained and opinion formed by debate, and that those in authority could act with far greater force if they knew that the voice of the profession was with them.

THE NEW WORKHOUSES AT LADYWELL, LEWISHAM. — These new buildings, erected by the St. Olave's Board of Guardians to provide accommodation for the aged and infirm poor of Lewisham, will be opened by the Prince and Princess of Wales on July 12th.

A GIFT TO BOURNEMOUTH.—Mr. Robert B. Scarlett, proprietor of the Shelley estates, on June 5th presented to the Mayor, in the presence of a large assembly of the inhabitants, as a gift to the borough in perpetuity, the new pleasure grounds on the cliff front.

COST OF VACCINATION.—At the last meeting of the Barnstaple (Devon) Board of Guardians it was reported that there had been 769 cases of successful vaccination during 1899, against 559 in 1898, the cost for 1899 being £434, and that for the previous year amounting to £122.—At the last meeting of the Merthyr Tydvil Board of Guardians one of the members said that comparing the year 1898 with 1899 the fees of the public vaccinators in the union had advanced from £285 to £905, and the fees of the vaccination officers from £101 to £180. It was decided to petition the Local Government Board to amend the Vaccination Order with a view to the reduction of the fees.—At the last meeting of the Neath (South Wales) Board of Guardians a letter was read from the Local Government Board in reference to the suggestion of the guardians for a reduction of the fees of the public vaccinators. The Local Government Board stated that it was intended at present not to reduce these fees, as under the new system the duties of public vaccinators had become so arduous.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.—The monthly meeting of this society was held on May 29th, at 12, New-court, Lincoln's Inn. The report of the Charity Commissioners in reference to the Leek Cottage Memorial Hospital, concerning which complaint had been made by the society on behalf of one of its members, was laid before the council, several alleged irregularities being dealt with therein. The council authorised the formation of a new division of the society for the province of Ulster, and approved the list of officials, Dr. Alexander Dempsey of Belfast being the first president and Dr. S. W. Allworthy the secretary. Steps were reported to have been taken for the formation of a Yorkshire division. The secretary reported that the General Medical Council had decided to erase from the Dental Register the name of a dentist who had been charged by the society with advertising, this being the first instance in which the General Medical Council had so exercised its powers. 166 new members had joined the society since the annual general meeting in April. A satisfactory financial report was submitted.

ANNUAL MEETING OF THE BRITISH MEDICAL TEMPERANCE ASSOCIATION.—The annual meeting of this association was held on June 12th at the Examination Hall, Victoria Embankment, London, after a reception by the President (Professor Sims Woodhead) and council of medical and scientific delegates to the World's Temperance Congress which was being held in the same building. The annual report was read by the honorary secretary, Dr. J. J. Ridge, and showed an increase both of members and student associates to 487 and 515 respectively. The report expressed the hope that as it had been conclusively demonstrated that men could do harder and more continuous work without than with alcohol, the rum ration should be abolished and the canteen purged from intoxicating drinks. It was announced that a Manchester branch had been formed of which Dr. A. T. Wilkinson had been elected president and Dr. Gray Clegg honorary secretary. Dr. Legrain and Dr. Boisser of Paris were elected honorary members of the association. Votes of thanks were accorded to the President and officers. Previously to the meeting a demonstration, with the aid of the electric lantern, had been given by Dr. Ridge in the lecture theatre of Scientific Reasons for Total Abstinence. He showed that healthy cell-life, both vegetable and animal, was impossible in the presence of minute quantities of alcohol, while by its interference with oxidation and the removal of waste products it injured the proper performance of every function. A novel experiment shown was the influence of even 1 per cent. of alcohol on the oxygen-producing function of the chlorophyll of water-plants, which it greatly diminished. The presence of alcohol, while it lowered vital function, even of the yeast which produced it, favoured and accelerated decomposition. The cumulative effect of small "moderate" doses was proved by the experience of life assurance offices and friendly societies, the difference in favour of the abstainers being much more marked after the age of 60 years, when the degenerations caused by alcohol had had time to take place. Diagrams prepared by Dr. Legrain were shown indicating how the increasing consumption of alcohol in France and Belgium was accompanied by the increase of crime, &c., and the proportion of conscripts rejected, these diminishing in Sweden and Norway, where the amount of alcohol consumed was lessening. There was a large attendance at this demonstration.

NATIONAL SANATORIUM FOR CONSUMPTION, BOURNEMOUTH.—The annual general meeting of governors of this institution was held at the Westminster Palace Hotel on June 13th. In the unavoidable absence of the Earl of Eldon (the President), Mr. Arthur F. Jeffreys, M.P., occupied the chair. It was resolved that the report and statement of accounts for the year 1899, as submitted, should be adopted and printed. Sir Edward H. Hulse, Bart., the Hon. T. A. Brassey, and Mr. D. H. W. Robson-Burrows were appointed trustees. The report showed that there was a debt of £655 for the building of a new sanitary wing at a cost of £1000, and that the ordinary annual expenses had been increased to the extent of about £200, due mainly to the expenditure requisite for efficiently carrying out the open-air treatment, and that this further sum would be required to meet the expenses of the present year. With the concurrence of the President, and of the Earl of Mount Edgcombe and Lord Wimborne, the vice-patrons, it was resolved that a special appeal should be issued to the general public for donations and subscriptions.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ALLEN, V. F., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Pentney Sanitary District of the Freebridge Lynn Union.

ANDERSON, W., M.B., C.M. Edin., has been appointed a Public Vaccinator for the District of Wairau, New Zealand.

BELL, H. T. S., F.R.C.S. Eng., has been appointed Health Officer at Wallungarra, Queensland.

BINNEY, E. H., M.B., Ch.M. Syd., has been appointed Honorary Surgeon to the Children's Hospital, Sydney, New South Wales, vice W. Chisholm, resigned.

SNELL—REID.—On June 14th, at the Roxburghe Hotel, Edinburgh, by the Rev. Alexander Badenoch, M.A., assisted by the Rev. Bernard J. Snell, M.A., B.Sc., Ernest Hugh Snell, M.D., B.Sc., of Coventry, to Mary Katharine, second daughter of the late William Reid of Dunfermline, N.B.

DEATHS.

ALTHAUS.—On June 11th, at Queen Anne-street, Cavendish-square, W., Julius Althaus, M.D., M.R.C.P. Lond., aged 67 years.

EDWARDS.—On June 6th, at Felixstowe, George Cordy Edwards, M.R.C.S., late of Ipswich, in his 81st year.

LIGHTFOOT.—On June 5th, at Saville-place, Newcastle-on-Tyne, suddenly, Charles L. Lightfoot, M.D., M.R.C.S., aged 38 years.

MERRYWEATHER.—On June 11th, at Guisborough, Yorkshire, James Merryweather, M.R.C.S., aged 68 years.

WILLIAMSON.—On June 6th, at Eldon-square, Newcastle-on-Tyne, George Edward Williamson, F.R.C.S. Eng., aged 48 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE SEXUAL QUACK.

WE have from time to time in these columns animadverted upon the circulars of "Dr." Bell, of the degraded blackguard who styles himself the "Reverend" David Jones (THE LANCET, Dec. 19th, 1896, p. 1774), of Madame Frain, and others, but for barefaced filth we have rarely seen anything to come up to a circular issued by an Oriental named Kabiraj Jasoda Handan Sircar whose wares are sold in Calcutta. According to the circular this person banks with Messrs Thacker, Spink, and Co., an announcement which may or may not be true. Abominable as the circular is it has one good point—namely, it is quite free from the disgusting cant and appeals to the Almighty which disfigure the effusions of David Jones. Kabiraj Sircar is an accommodating person. Does anyone wish for a large family he can obtain the desired result by taking or giving to his wife the Great Rasanayam at four rupees per ounce. Half an ounce is to be taken daily for apparently 41 days. Should he not wish for children, "use our linen which we will tell you how to use in order to be sterile." *The* panacea, however, seems to be a drug called G. Palashiam, which is nominally for ovarian tumour, but "if you do not know the name of your disease please state the nature of the pain you feel and the colour of the discharge." Oriental sexual imaginings are far more vivid than among the natives of the colder north and we make no doubt that Sircar drives a very good trade, neither, so far as we know, is there any way to stop him.

"DEATHS UNDER CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—The following extracts throw an interesting sidelight upon the matter which has been debated in your columns under the above heading. They are somewhat bewildering to a student of anæsthesia. The first three are taken from an article on chloroform by Professor Ogston in the "Encyclopædia Medica" (vol. i., 1899). The second three are taken from an article on anæsthesia, by Dr. Silk in Cheyne and Burghard's "Manual of Surgical Treatment" (part i., 1899). 1. "There is no advantage in using 'pure chloroform,' that is, chloroform prepared from pure alcohol. 'Methylated chloroform,' manufactured [from methylated spirit, is as good, as pure, and as safe and costs considerably less." 2. "The position of the patient should, if possible, be recumbent—on the back with a low pillow under the head; but this may be departed from if there be any sufficient reason, as in minor operations on the throat where roof light is not obtainable." 3. "No inhaler is so good as a clean towel. ..... The writer thinks it best to cover the entire face with the towel. ..... By thus covering the face a view of the expression and changes of colour, which may be helpful to a timid and experienced chloroformist, are excluded. but to the skilled administrator these are not things of much importance. 4. "Chloroform has a chemical formula of $CHCl_3$. Its spec. grav. should be 1·497, and only that made from pure alcohol should be employed; the so-called methylated chloroform is inadmissable for anæsthetic purposes." 5. (α) "With regard to position an emphatic protest must be entered against any attempt being made to administer chloroform to a patient sitting in a chair. This protest is necessary, because it is still occasionally used for tooth extraction with the patient in the ordinary dental position; when chloroform is inhaled the patient should always be recumbent." (β) "Neither chloroform nor any mixture containing that drug should be used with the patient sittting up in a chair; such a proceeding is absolutely unjustifiable." 6. "The ideal condition of a patient under chloroform should be somewhat as follows—viz., colour good or slightly pallid, respirations regular, fairly deep, slightly accelerated, quiet, or with a slight soft snore; eyeballs fixed or rotating very slowly from side to side, pupils moderately contracted and sluggishly sensitive, corneal conjunctivæ insensitive. ..... Blueness of the lips, cheeks, ears, &c., is quite unwarranted, as it indicates that the vapour is being given in far too great a strength, and air must at once be supplied. Some patients become very pale under any anæsthetic which contains chloroform, and if this pallor is gradually displaced by an ashen-grey hue it is an indication that the circulation is failing and the anæsthetic must be at once withdrawn, and, if need be, more energetic measures taken."

I am, Sirs, yours, faithfully,

West Ham Hospital, E, June 11th, 1900. SIDNEY VINES.

WORD-BLINDNESS—APHASIC PARALYSIS.

To the Editors of THE LANCET.

SIRS,—At page 1699 of THE LANCET of June 9th, there is an interesting query as to the possible use by aphasics of raised type, as used by the blind, and by which the blind read by touch instead of by sight.

If Mr. Menteath will refer to a paper by me on "Will-making in Aphasic Paralysis" in the *British Medical Journal* of March 31st, 1900, he will find that the use of raised letters by aphasics, both for enabling acute aphasics to make their wills and to enable

chronic aphasics to re-develop the faculty of language in the right hemisphere, has been dealt with. The method there described for the use of printed cards—as applying to aphasics in whom there is receptivity for ingoing ideas but inability to make the mind known to outsiders—was a notable success in my case. The use of raised letters for blind aphasics is also suggested and considered by me, and I have no doubt that there are some such cases in which the typewriter—made with raised key-letters for blind aphasics—may further serve such patients as mine was. But when we come to aphasics in whom receptivity for ingoing ideas also is impaired, if only to the extent of "word-blindness," used in its mental sense and not in the sense of blind aphasics, as I used it, the cases are less promising. Here the mind is profoundly affected, to a greater or less extent, over the various channels of receptivity. But the trial of raised-letter print, or of a special typewriter made with bold raised key-letters would be an interesting experiment, and I have intended to try the experiment in the next suitable case of aphasic paralysis which may fall under my care. Block letters—such as are cemented on to plate-glass shop windows or such as are used to teach young children to spell—may enable certain aphasics to spell out or indicate the names of things, places, or persons of which they have a clear conception but cannot give utterance to, neither by speech nor writing. Gesture is unavailable for concrete substantives. For such substantives the mind thinks in images and names are lost early.

In the case described in my paper, considerable property, real and personal, was devised by a will made at my suggestion and design by means of printed cards. These cards were of three categories. 1. A list of the properties to be disposed of. 2. A list of offices to be assigned—trustees, executors, guardians, &c. 3. A list of all the testator's relatives, friends, and objects in which the testator was likely to be personally interested or which might have a claim for bequests. The cards each contained one item—property, office, or person. By a method of sorting out and combining these cards an aphasic lady was enabled to make her will perfectly and to dispose of all her property. Full details of the procedure will be found in my paper but it is too long to abstract here. I may add that in this case counsel advised the executor that the will, being without precedent and passing real property, should be proved in solemn form before the Court of Probate with notice to all such persons as might have profited by the rejection of the will. The result was a sort of action-at-law in open court before the learned President of the Probate Court, Sir Francis Jeune. The President formally approved of all that had been done and admitted the will to probate. This, therefore, becomes a leading case in will-making. In future there will be no reason why aphasics of the same type as my patient should not always have the opportunity for making their wills.

There is a very valuable and interesting chapter upon the jurisprudence of aphasia, will-making, and other topics in Sir Frederick Bateman's scholarly and researchful work on "Aphasia." I should be glad to place any brotherly help I could give at the disposal of any other practitioner who may happen to have in his charge one of these somewhat rare cases of aphasia. I should also be much obliged for an opportunity to see any such case.

I am, Sirs, yours faithfully,

Manchester-square, W., June 10th, 1900. JAMES EDMUNDS.

THE LOCAL GOVERNMENT BOARD AND VACCINATION.

To the Editors of THE LANCET.

SIRS,—In vaccinating will the following steps satisfy the requirements of the Local Government Board regulations? 1. Wash the arm with carbolised lint, using hot water and carbolic soap. 2. Thoroughly heat the lancet in a spirit flame. 3. Expel the lymph with an artificial blower. 4. Protect the surface with an antiseptic pad until the scabs fall off.

I am, Sirs, yours faithfully,

June 9th, 1900. VACCA.

*** Generally speaking we think the precautions referred to would merit the Government award. But the Government inspector would doubtless inquire as to whether the public vaccinator was careful to examine all children submitted to be vaccinated, and he would, we expect, wish to know the precise practice of the public vaccinator with regard to the use of antiseptic pads. We conclude that our correspondent does not wish to imply that one pad would suffice for the whole period in question. So, too, we infer that the lancet is to be thoroughly cleansed as well as sterilised in the flame.—ED. L.

THE PREVENTION OF TUBERCULOSIS: A CHEAP NOTIFICATION FEE.

To the Editors of THE LANCET.

SIRS,—"The Sanitary Committee" of Plymouth "recommended that the scheme should be adopted, and that notifying medical practitioners should be allowed a fee of 2*s.* 6*d.* for each private patient and a *fee of* 1*s.* for each parochial or dispensary patient notified. The recommendation was *unanimously* adopted."(THE LANCET, June 9th, 1900, p. 1675.) Surely it is bad enough to have to notify scarlet fever or erysipelas at such ridiculous fees as 1*s.* Still, both of these diseases are usually recognised at a glance when well marked, but notwithstanding this fact mistakes are often made. What then shall we say of phthisis? the diagnosis of which, in the early stages, is surrounded with so much difficulty and uncertainty, and where so much time is required not only for the careful examination but for the undressing and dressing in order to expose the thorax. I almost venture to doubt whether any medical man *capable* of making a *correct* diagnosis would accept such poor remuneration. Need we be surprised at the existence of 6*d.* dispensaries in our midst? Cheap (?) food and cheap (?) clothes are bad enough, but still, we can throw these away or survive them. But cheap (?) medical advice means, as a rule, lowering of professional dignity and skill and the speedy enrichment of the undertaker. Even the veterinary surgeons charge more for attending our domestic animals. I am, Sirs, yours faithfully,

Putney, S.W., June 9th, 1900. ALBERT S. MORTON, M.D. Durh.

THE QUESTION OF HORSE AMBULANCES.

WITH reference to an annotation in THE LANCET of June 2nd, p. 1604 we understand that Bolton possesses a horse ambulance which is kept at the fire-engine station, with the result that in the case of a street accident the patient is quickly conveyed to the hospital. By this means much suffering is prevented and perhaps many lives are saved, but it is obvious that the hospital or infirmary is the most desirable place for the ambulance to be stationed in order that a qualified attendant may accompany the vehicle.

Justitia.—The letter has reference apparently to some particular episode rather than to the general attitude of the public and the colonial practitioner towards each other. All the circumstances of the case must be made clear to us or we cannot appreciate the justice of our correspondent's deductions.

Mizpah is informed with regard to his recent inquiry for a copy of Albert Smith's "Physiology of the Medical Student" that if he will communicate with Mr. Edward Baker, 14, John Bright-street, Birmingham, he may be able to obtain a copy of the book for about 6*s.*

Student.—The school named would be an excellent one for the purpose. Our correspondent should consult the Student's Number of THE LANCET. The last issue was dated Sept. 2nd, 1899.

Dr. J. Aikman.—The tract is practical and timely and should prove of value.

During the week marked copies of the following newspapers have been received: *Public Health Engineer, Science Siftings, Jersey, Express, Westminster Gazette, Morning Advertiser, East Anglian Daily Times, Hereford Times, Norfolk Daily Standard, York Daily Herald, Evesham Journal, Western Mail, Leeds Mercury, Blackburn Daily Telegraph, Brighton Gazette, Kent Messenger (Maidstone), Yorkshire Post, Irish Times, Glasgow Herald, Times of India, Pioneer Mail, Manchester Guardian, Yarmouth Advertiser, Liverpool Daily Post, Builder, Citizen, Architect, Scotsman, Kentish Express, Bristol Mercury, Beverley Guardian, Sanitary Record, Cornish Times, Melbourne Leader, Local Government Chronicle, Mining Journal, Reading Mercury, Hertfordshire Mercury, City Press, Bedford Record, Dean Forest Guardian, British Realm, Bicester Herald, Boness Journal, Monetary Times, Huddersfield Chronicle, Surrey Advertiser, Walsall Observer, Local Government Journal, Weekly Free Press and Aberdeen Herald, Sunderland Morning Mail, Bradford Observer, &c., &c.*

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.).

WEDNESDAY (20th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.)

THURSDAY (21st).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.).

FRIDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Lonpon Throat (2 P.M. and 6 P.M.).

SATURDAY (23rd).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (20th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Mr. W. Carruthers: Demonstration on the Structure of some Palæozoic Plants (with sections of the plants thrown on the screen).

THURSDAY (21st).—ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND (Medical School of the Owens College, Manchester).—10.30 A.M. Exhibition of Specimens. 11 A.M. to 1.30 P.M. Lantern Demonstrations by Dr. R. J. Berry, Prof. Dixon, and Dr. T. H. Bryce. Cases and Specimens will be shown by Prof. Fawcett. Papers:—Prof. Birmingham: Some Points in the Anatomy of the Digestive System.—Dr. Armour; A Note on the Genital Apparatus of the Jerboa. Council Meeting.

FRIDAY (22nd).—ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND (Medical School of the Owens College, Manchester).—10.30 A.M. Exhibition of Specimens. 11 A.M. to 1.30 P.M. Papers:—Dr. C. J. Patten: Note on the Configuration of the Heart in a Man and some other Mammalian Groups.—Dr. P. Thompson: On the Arrangement of the Pelvic Fasciæ and their Relationship to the Levator Ani.—Prof. Paterson: A Preliminary Note on the Development of the Sternum. Specimens, Preparations, Lantern Slides, and Microscopical Preparations will be shown by Prof. Paterson, Dr. A. Robinson, and Prof. Young.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (18th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. C. Fox: Consultation. (Skin.)

LONDON THROAT HOSPITAL (204, Gt. Portland-street, W.).—4.30 P.M. Dr. F. Potter: Hoarseness and Aphonia. (Post-graduate Course.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. A. E. Saunders: Diseases connected with Insanitary Surroundings.

TUESDAY (19th).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. F. W. Mott: The Degeneration of the Neurone. (Croonian Lecture.) Lecture I. Syllabus:—Definition of the term "Neurone."—The Neurone Theory *versus* the Theories of the Diffuse Network of Gerlach and the Diffuse Nerve Network of Golgi.—The Structure of the Nerve Cell: a Stainable and Unstainable Substance revealed by the Nissl Method; Significance of the Nissl Granules.—Nerve Fibres; Correlation of Function and Myelination.—The Myelin Sheath; its Origin, Functions, and Relation to the Sheath of Schwann. Brief Historical Introduction:—The Researches of Waller upon Secondary Degeneration of Peripheral Nerve Fibres.—The Researches of Türck upon Secondary Degeneration of the Fibres of the Central Nervous System.—Disuse Atrophy.—Dickinson's Observations upon the Secondary Atrophy following Amputation.—The Gudden Atrophy Method.—Primary Degeneration the Outcome of the Cellular Theory of Virchow; its Relation to the Doctrine of the Neurone.—Practical Importance of the Neurone Doctrine.—The whole Central Nervous System in Physiological if not in Anatomical Continuity.—The Variable Resistance to the Spread of Excitation.—The Neurones Divided into Three Groups, Afferent, Efferent, and Association.—The Physiological Inter-relationship of these Groups and their Functional Equilibration.—Anatomical Correlation of Associated Systems of Neurones.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. H. Campbell: Consultation. (Medical.)

WEDNESDAY (20th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—5 P.M. Dr. D. Ferrier: "Jacksonian Epilepsy." 5-7 P.M. Dr. W. J. Horne: Class. Practical Rhinology and Laryngology. Demonstration VI.

EVELINA HOSPITAL (Southwark-bridge-road, S.E.).—4.30 P.M. Dr. G. Carpenter: Clinical Demonstration of Selected Medical Cases. (Post-graduate Course.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Horton-Smith: Clinical Varieties of Phthisis.

THURSDAY (21st).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. F. W. Mott: The Degeneration of the Neurone. (Croonian Lecture.)—Lecture II. Syllabus:—1. Effects of Injury of a Nerve upon the Cells of Origin.—2. Effects of Temporary and Permanent Failure of the Blood-supply upon the Cerebral Neurones as Studied by Ligation of the Cerebral Arteries.—3. Experimental Anæmia of the Spinal Cord.—4. Effects of Severe Hæmorrhage, Morbid Processes, and Poisons causing Anæmia.—5. The Bio-chemical Changes in the Neurone produced by Hyperpyrexia.—6. The Effects of Toxic Conditions of the Blood and Lymph upon the Neurone as Studied in Certain Experiments.—7. Selective Influence of Poisons upon the Neurone.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

CHARING-CROSS HOSPITAL.—4 P.M. Dr. A. Routh: Gynæcological Demonstration. (Post-graduate Course.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. A. E. Saunders: Diseases connected with Insanitary Surroundings.

FRIDAY (22nd).—MEDICAL GRADUATES COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. StClair Thomson: Consultation. (Throat, Nose, and Ear.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied, Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Dr. J. Aikman, Birnam, Guernsey; Anatomical Society of Great Britain and Ireland; Messrs. Arnold and Sons, Lond.; Mr. A. Anderson, York; Dr. Alvernhe, Paris; A. B., Lond.; Aerators, Ltd., Lond.

B.—Mr. C. Birchall, Liverpool; Bridgwater Infirmary, Hon. Secretary of; Messrs. Bowen and Symes, Weymouth; Beckenham and Penge Medical Society, Hon. The Croonian Lectures

ON

THE DEGENERATION OF THE NEURONE.

Delivered before the Royal College of Physicians of London

BY FREDERICK W. MOTT, M.D. LOND., F.R.S.,

PATHOLOGIST TO THE LONDON COUNTY ASYLUMS; PHYSICIAN-IN-CHARGE OF OUT-PATIENTS, CHARING-CROSS HOSPITAL.

LECTURE I.[1]

Delivered on June 19th, 1900.

MR. PRESIDENT AND GENTLEMEN,—Allow me to thank you for the great honour you have done me in asking me to give these lectures. I feel the responsibility all the more in lecturing upon the subject I have chosen, when I look back upon the eminent neurologists who have given these lectures on previous occasions. I cannot hope to attain to the philosophy of Hughlings Jackson or the epoch-making researches of Ferrier, but I will endeavour to put before you some thoughts, experiments, and observations relating to degeneration of the nervous system which have occupied my attention during the past three or four years.

DEFINITION OF THE NEURONE AND THE NEURONE THEORY.

Before considering the neurone under pathological conditions it is necessary to define the term, to make a few general remarks upon the neurone theory, and to describe our present knowledge of the structure of the neurone. The term "neurone" was introduced by Waldeyer for the nerve-cell and all its processes, including the protoplasmic processes or dendrons and the single axis-cylinder process with its cone of origin, its collaterals or side branches, and its terminal arborisation. The theory of the neurone put forward by Waldeyer[2] is that the nervous system consists of innumerable such anatomically independent nervous units in contiguity but not in continuity. There is interlacing of the processes, but no nerve network.

THE NETWORK OF GERLACH.

In 1871 Gerlach,[3] by the gold method of staining, showed an intricate network in the grey matter; he came to the conclusion that the protoplasmic processes of the nerve-cells were all connected in a delicate network, and that out of this network strands of fibrils joined together to form fibres which passed out of the posterior roots and became sensory nerve-fibres. For 15 years this theory was accepted; then Forel[4] and His,[5] by their studies respectively of degeneration and of the development of the nervous system in the embryo, completely overthrew the doctrine of Gerlach. Forel pointed out the limitation of secondary degeneration; and by the Gudden atrophy method showed that degeneration or atrophy did not pass beyond a cell station when the fibres which arise from those cells are cut through; and he claimed that the nervous system consisted of independent cellular units. Forel also called attention to the remarkable work of Golgi,[6] and although he opposed the diffuse nerve network theory put forward by that authority yet he recognised the great value of the researches made by his new chrome silver method. About this time Professor His published his researches upon the development of the nervous system, and he showed that the axis cylinder and the other processes of the nerve-cell were outgrowths of the cell protoplasm, and the apparent nervous network was really only an interlacing of innumerable cell processes.

The chrome silver method of Golgi was later adopted by Ramon y Cajal,[7] Retzius,[8] Kölliker,[9] Lenhossek,[10] Van Gehuchten,[11] and many others, and their researches *apparently* demonstrated the fact that the whole nervous system consists essentially of independent anatomical units, and the neurone theory seemed indisputably established. No matter how multitudinous and complex the branches of the cell might appear yet they never anastomosed with the branches of other cells; like the trees of a forest there is contiguity but not continuity. Within the last few years, however, owing to the researches of Apáthy,[12] Bethe,[13] Dogiel,[14] and Nissl,[15] there is a tendency on the part of some authorities to go back to a diffuse network theory. Some important researches by Held,[16] also have been put forward to disprove the neurone theory. In my opinion, however, one can still accept the neurone theory and admit the truth of Held's observations, namely, that the terminal arborisation of the axis-cylinder process of one neurone forms protoplasmic concrescences by fusion with the cell body and dendrons of another. This of course implies continuity of the protoplasm of one neurone with another, but trophically and genetically the two are independent, and it is merely a question of degree of contact of the protoplasm of one with the other. Held agrees with other investigators that in embryonic tissues, and even in early life, the neurones are entirely independent of one another. This independence he can determine by a line of demarcation at the points of contact due to a difference in refraction. This refractive limiting line is, however, not demonstrable in the adult, and he comes to the conclusion that during the process of growth the protoplasm of related neurones fuses. Turner and Hunter[17] by the *intra vitam* methylene blue method, however, come to a different conclusion to that of Held, for they have shown that the terminal arborisations of the axons of one set of neurones end in a basket work around the cells of functionally related neurones, but do not form protoplasmic connexions.

The neurone theory has always been opposed by Golgi, who maintained that his method demonstrates a diffuse network formed by the collaterals of the axons; but it is especially the work of Apáthy and Bethe which has led authorities such as Nissl to renounce the neurone theory. Lugaro,[18] Lenhossek,[19] Barker,[20] Van Gehuchten, and many other authorities, on the other hand, maintain that the observations of Apáthy and Bethe do not warrant the general conclusion that nerve-cells are connected with each other by means of their primitive fibrils. Moreover, Apáthy has only demonstrated a continuous network of elementary fibrils outside the nerve-cells in *invertebrates;* such an arrangement has not yet been proved to exist in vertebrates; in fact, there is the strongest histological evidence that it does not exist. The study of the development of the nervous system and secondary degeneration to my mind shows the genetic and trophic independence of the nervous units; and in spite of the opposition which the "neurone theory" has lately met with in some quarters it is still acceptable.

THE STRUCTURE OF THE NERVE-CELL AS REVEALED BY THE NISSL METHOD.

The Nissl method is generally used for demonstrating the internal structure of the protoplasms of the nerve-cell and its processes, but before referring to pathological conditions as studied by this method it is necessary to make a few remarks upon the method itself, and the appearances presented by normal nerve-cells.

Nervous tissue, which has been fixed in 96 per cent. of

alcohol, formol solution, or corrosive sublimate solution, and of which sections have been cut and stained by basic aniline dyes—e.g., methylene blue, toluidine blue, thionine, and by many other modifications of the original method, shows pictures of the nerve-cells stained in a characteristic manner. If we take as a typical structure an interior horn cell stained by this method we shall observe the following characteristics. The body of the cell is stained a deep blue, but not uniformly, for the staining presents a mosaic appearance, due to little stained polygonal areas disposed more or less concentrically round the nucleus and separated one from another by an unstainable substance. Towards the periphery of the cell these polygonal stained areas become elongated, and upon the dendrons they are fusiform, their long axes being parallel to the processes. At one portion of the cell, if it is entire, a process—the axon—will be observed which does not possess any stainable substance, so that we see that this method differentiates two substances—a chromatic stainable substance and an achromatic substance.

Researches to be afterwards alluded to have shown that the stainable substance is a nucleo-proteid, a substance which contains phosphorus, but in less proportion than the nucleic acid of the nucleus, and the fact that the stainable substance is found around the nucleus may indicate that it is a result of the active metabolism of the nucleus on the surrounding protoplasm. By some authorities it is considered to be a store of nutriment, by others a store of energy; and on this account it has been termed by Marinesco "kinetoplasm." The changes which this substance undergoes, as studied by the Nissl method, show that it has some important functional relationship to the metabolic activity of the neurone; it is, however, not the essential substance. The unstainable substance, on the other hand, is essential, and consists of an organised network of delicate fibrils which extend into the dendrons, forming a network in the cell substance and passing out again in the axis-cylinder process. Consequently there is probably a direct protoplasmic fibrillary continuity between the dendrons and the axons. This was originally stated to be so by Max. Schultze.[21] The nucleus is apparently of simple structure and is permeated by irregular strands of karyo-plasm which form a coarse network; it is apparently situated in the centre of the cell and contains a nucleolus or several nuclear bodies, which, together with the nuclear membrane, stain with a basic dye.

THE SIGNIFICANCE OF THE NISSL GRANULES.

There is a vast amount of literature concerning the stainable bodies called "Nissl granules." They were at one time believed to be an essential constituent of the living cell, but the researches of Hardy have shown that there is a great difficulty in deciding to what extent structure demonstrable in the fresh or fixed state is the product of the chemical and physical changes which constitute the death changes or due to the action of fixatives. Moreover, Held[22] has shown that the *intra vitam* methylene blue method does not reveal Nissl granules in the cells. The stainable (chromatic or chromophilous) substance, therefore, is probably not present in the living cell in the definite form which we see it when the tissues are freed and stained by the Nissl method. It must not, however, be assumed, therefore, that the method is unreliable as a means of studying the bio-chemical changes occurring in the protoplasm of the nerve-cells, for providing certain precautions are taken, it has proved most valuable in demonstrating functional and organic changes occurring in the nerve-cells as a result of injury of the axon or of toxic substances in the blood.[23]

The large motor cells of the cord and brain are the best for studying the changes in the cell protoplasm, because in these structures the stainable substance appears in normal tissues as if it consisted of formed elements (Nissl granules) in the body of the cell and in the dendrons. I have always looked upon these elements as being due to a death-change of the fluid plasm of the cell whereby the nucleo-proteid substance contained in it is thrown down as a fine precipitate, much the same as myosin is precipated from myosinogen. If this substance is abundant in the fluid plasm it produces when precipitated these definite forms, because it fills up the spaces of the unstainable intracellular fibrillary reticulum. "Chromatolysis" is the term which is frequently applied to designate the disappearance or disintegration of these Nissl granules, and there may be various stages of chromatolysis. Usually the process begins at the periphery of the cell and on the dendrons. The stainable substance may be greatly diminished or entirely lost in these situations, or, again, the granules may be seen to consist of fine particles, their definite outline being lost, and in advanced chromatolysis the whole cell may be so affected.

The condition and amount of the stainable substance may be an indication of the functional activity of the cell, and it is conceivable that diminution of the nucleo-proteid colourable substance is the expression of the diminution of the vital interaction of the highly phosphorised nucleus upon the surrounding cell protoplasm. I do not consider that chromolytic changes alone are indicative of cell destruction, for, as I shall show later, most marked chromolytic changes may occur in the cells of origin after section of a nerve and yet the cells may completely recover.

Changes of the cell in form and size may be recognised—e.g., swelling or shrinking, due, no doubt to an alteration of the vital osmotic reaction of the cell-protoplasm to its fluid environment; likewise the nucleus may be clear and swollen or shrunken, the nuclear membrane in the latter case being thrown into folds. Very frequently the nucleus becomes eccentric in position instead of being situated in the centre of the cell, and owing to abnormal osmotic relations and protoplasmic change it may even be extruded and this of necessity would cause death of the cell. Another indication of death of the cell-protoplasm is revealed by uniform staining of the whole cell and its processes. It occurs in hyperpyrexia and in the coagulation necrosis resulting from obstruction of the blood-supply for a sufficient length of time to cause the death of the protoplasm.

The importance of the chemical and histological changes occurring in the myelin sheath in degeneration of the nervous system, the difference of opinion as to its origin, and the important discoveries which have been made by Flechsig, Bechterew, and others with regard to correlation of structure and function necessitate a somewhat full account of

THE MYELIN SHEATH AND NUCLEATED SHEATH OF SCHWANN.

Nerve-fibres are of two kinds, grey and white. The grey sympathetic fibres differ essentially from the white fibres by the existence in the latter of a complex phosphoretted fatty substance lying between the nucleated sheath of Schwann and the axis-cylinder process. The white fibres of the central nervous system differ from the peripheral white fibres by not possessing a nucleated sheath of Schwann. The myelin is probably contained in a neuro-keratin reticulum and this reticulum is much more abundant in the white matter of the central nervous system than in the peripheral, for Kühne and Chittenden[24] have shown that there is about eight times as much neuro-keratin in the white matter of the central nervous system as either in the grey matter of the central nervous system or the white matter of the peripheral nervous system. In 1884 Weigert introduced his hæmatoxylon method for staining the myelin sheath and by means of this Flechsig[25] and his pupils were able to show that certain tracts of fibres of the central nervous system were developed earlier than others. This method and its various modifications (Pal, Marchi-Pal, and Schäfer) have yielded the most valuable results. The different tracts of the posterior columns of the spinal cord were found to be myelinated at different periods, and it was owing to Flechsig's studies that those of endogenous origin (that is, arising from cells *within* the spinal cord) were differentiated from those which are exogenous (that is, have their trophic and genetic centres in the cells of the posterior spinal ganglia). The practical outcome of this research was the modern idea of the pathology of tabes, for it was shown that the exogenous fibres were alone atrophied in tabes, while the endogenous fibres—viz., cornu-commissural zone of Westphal[26] and the median oval area of Flechsig—were spared, these tracts having their trophic and genetic centre in cells within the grey matter of the cord. These facts were recognised as being incompatible

[22] Ueber Experimentelle Reizung des Nervenmarks.
[23] Since the method is a *comparative* one great care must be exercised in practising the same details of method of fixation, cutting, and staining the morbid tissues and the normal tissues with which they are to be compared. Again, it is absolutely essential that the tissues examined should be fresh and free from any chance of post-mortem decomposition.

[24] Ueber das Neurokeratin, Zeitschrift für Biologie, 1890, Band viii.
[25] Ist die Tabes Dorsalis eine system Erkrankung? Neurologisches Centralblatt, 1890, vol. iii.
[26] Goldscheider: Die Bedeutung der Reize für Pathologie und Therapie im Lichte der Neuronlehre, 1898.

with the prevalent view that the degeneration was caused by a sclerosis or overgrowth of glia tissue in the posterior columns, or by vascular changes; but they pointed especially to a nutritive failure in the trophic and genetic centre by which the outlying projections of the axis-cylinder processes and their myelin coverings underwent a regressive atrophy; in fact a metamorphosis of the neurones occurred, the inverse of their development.

CORRELATION OF FUNCTION AND MYELINATION.

Again, the researches of Flechsig have demonstrated the different centres of the central nervous system, in which tracts of nerve-fibres have their origin or termination; and it is to the application of this method by Flechsig that we owe one of the most exact, and one of the most valuable, contributions to the structure and functions of the human brain. The method depends upon the fact that there is a correlation between the functions of systems, groups, and communities of neurones and the myelination of their axons; thus, in the brain and the spinal cord of the fœtus, the new-born child, and the developing infant, tracts of fibres are myelinated with definite regularity at successive periods of time, indicating ontogenetically their functional and structural development. The myelin sheath appears three or four months after the development of the axis-cylinder process; for example, a bundle of axis-cylinder fibres demonstrable by the Golgi chrome-silver method at the ninth month would not show a myelin sheath until three months or more after birth. When the myelination of a nervous system is complete further information by a study of the condition of the myelin sheath can only be obtained by observations made upon secondary degenerations produced either by disease or experimentally, and to this subject I shall refer later with especial reference to the Marchi method. To return, however, to the process of myelination. In the central nervous system, the afferent projection fibres are myelinated before the efferent, and it is a fundamental principle that bundles of fibres of different physiological functions are myelinated at different periods of time. The whole afferent tract, conducting tactile, articular, muscular, and visceral sensations by the posterior columns, fillet, thalamus, and corona radiata, is myelinated at birth. These bundles of fibres have already (while the fœtus was in utero) been exercised in conveying impressions to the appropriate receptive centres in the Rolandic region of the cortex, the stimuli being provided by contact of the teguments with the maternal structures and as a result of reflex movements which commence at quickening; for every movement must necessarily be associated with alterations in tension of muscular, tendinous, and cutaneous structures, giving rise thereby to kinæsthetic impressions.

Moreover, the myelination commences first in those parts of the occipital lobe situated around the calcarine fissure, which we know corresponds to the function of vision, the relays of neurones which proceed to the cortex forming the afferent projection systems are earliest myelinated, as they are the first to be acted upon by stimuli which excite the nerve terminations in the skin, joints, tendons, and mucous surfaces of the developing fœtus. Thus, as shown in the diagrams, in the new-born child only the lower centres of the spinal cord, medulla, pons, corpora quadrigemina, optic thalamus, and certain areas of the cerebral cortex are myelinated. The cortical areas which are so myelinated are situated around the primary fissures and correspond to areas which are the end stations of the afferent projection systems; for example, the tactile motor area is situated around the fissure of Rolando; the olfactory, gustatory, and auditory around the Sylvian fissure; and the visual around the calcarine (see Figs. 1 and 2).

Flechsig has shown that at least two-thirds of the cortex cerebri consist of neurones of association, and according to him (although this does not meet with general acceptation) these association centres possess no neurones belonging to the afferent or efferent projection systems. In the fœtus of eight months the pyramidal fibres of the motor efferent system are still without myelin, but Ambron and Held[27] have shown by a new method of examining the condition of the myelin, by the effect produced on polarised light, that the motor fibres of the anterior roots are myelinated earlier even than the posterior roots.[28]

[27] Ueber Entwickelung und Bedeutung des Nervenmarks, Archiv für Anatomie und Physiologie, Abtheilung 1896.

[28] This method is a very ingenious one, and as it is not generally known I will describe it a little more fully. *Method.*—Held and Ambron take nerves of new-born animals, tease them in normal saline solution, and examine them in the following manner with polarised light. They place the two prisms at right angles and put the nerve in the same line as the "quartz plate," when it gives a purple colour. The myelinated nerve will appear red, orange, or yellow, according to the stage of myelination (red being the most advanced); these are the subtraction colours, whereas non-myelinated nerve and connective tissue give the addition colours violet, indigo, and blue. In this way they have examined all the nerves and they have arrived at the conclusion that the peripheral motor nerves are more advanced in myelination than the sensory nerves at early periods of development. Flechsig, as I have remarked, has shown—and they confirm this—that the reverse is the case for the central nervous system. They offer no explanation, but possibly it may be found phylogenetically that in the evolution of specialised reflex acts in the zoological series the motor fibres have acquired first the myelin sheath; or it may be that the sensory bundles are made up of fibres having different functions, and that these are myelinated at different periods of time; again, we know that a large number of fibres entering a muscle (Sherrington) are afferent in function.

In a second paper Held has shown the important influence stimulus has upon myelination, thus establishing still more fully the correlation of function and myelination. Cats, dogs, rabbits (animals which are born blind) were

FIG. 1.

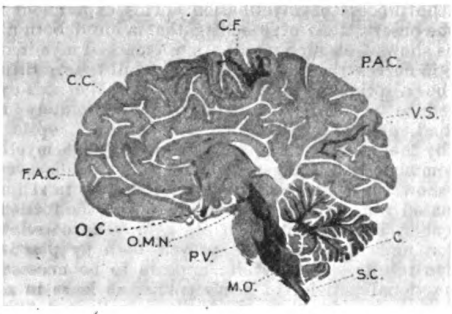

Diagram of vertical section through the brain of a new-born child stained by the Weigert method to show myelination of the fibres. All the parts which are dark contain myelinated fibres. Attention is particularly called to the rather faint deep staining about the central fissure which corresponds to the tactile motor area. It will be observed that the association centres are not myelinated. M O, Medulla oblongata. P V, Pons Varolii. O M N, Oculo-motor nerve. O C, Optic commissure. F A C, Frontal association centre. C C, Corpus callosum. C F, Central fissure. P A C, Posterior association centre. V S, Visual sphere. C, Cerebellum. S C, Spinal cord. It will be observed that the pyramidal efferent system is not myelinated.

experimented on in the following way. Light was admitted for varying periods to one eye by opening a lid, the other remaining closed. Examination of the optic nerve on the two sides under the same conditions showed a more obvious

FIG. 2.

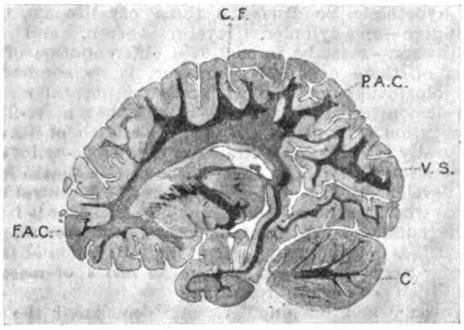

Diagram of vertical section of the brain of a child aged five months. The greater part of the brain now shows by the staining myelination of the white matter, showing development of the association centres. F A C, Frontal association centre. C F, Central fissure. P A C, Posterior association centre. V S, Visual sphere. C, Cerebellum. It will also be noticed that the corona radiata and internal capsule are myelinated.

myelination on the side exposed to light than on the other. The irritation which might be produced by opening the lid was not the cause of this difference, for an animal which had had the lid opened on one side and not on the other but which was kept in darkness showed no difference in myelination of the two sides. The obvious inference is that transmission of light impulses along the optic nerve had stimulated the process of myelination. This experiment agrees with the observations of Flechsig that a child born at eight months showed at nine months more marked myelination of the optic nerves than a child born at full time. Still there must be a primary innate tendency of the axis-cylinder to produce myelin, for a dog kept absolutely in the dark had, on the eighth day, orange-tinted optic nerve-fibres by the polarisation method, showing that myelination had commenced. Edinger[29] states that the discoveries of Kaes show that the cerebral cortex increases in richness of myelinated fibres for a long time, even to the fortieth year and longer, but diminishes in old age. The correlation of function and myelination is proved both by positive and negative results. The myelin appears to be necessary for the functional activity of nerve tracts, at least in animals which possess a nervous system with myelinated fibres, for the development of the myelin along particular tracts of fibres in the central nervous system proceeds in a manner *pari passu* with the development of function. Atrophy and degeneration of the myelin sheath in pathological processes, whether due to disuse atrophy, or to primary or secondary degeneration, are associated with marked disturbances appertaining to the functions of particular systems, groups, and communities of neurones.

THE HISTOGENESIS OF THE SHEATH OF SCHWANN.

This has been studied by many observers, and a paper has recently appeared by Gürwitsch[30] reviewing the work of previous observers and giving his own observation upon this subject. Küpffer,[31] Beard,[32] and Gegenbauer[33] believed that the axis-cylinder is developed from a chain of cells of ectodermal origin arranged in a series. Such an idea would conform with the researches of Apáthy upon invertebrates and is opposed to the axis-cylinder being an outgrowth of a nerve-cell situated either in the anterior cornua or the posterior spinal ganglia. If this hypothesis be true the three constituents of the nerve-fibre—axis-cylinder, myelin sheath, and sheath of Schwann—must be formed by a differentiation of protoplasm of these cells. If, however, it be admitted that embryological, morphological, and experimental researches have demonstrated that the axis-cylinder of a nerve-fibre is a prolongation of a nerve-cell, then the sheath of Schwann is genetically foreign and extraneous to the axis-cylinder; but the question arises, How, then, is the myelin sheath formed? Is it developed by the axis-cylinder, as in the central nervous system where the sheath of Schwann is absent, or is it formed by the nucleated sheath of Schwann? Another alternative is that it is developed by a metabolic interaction of the axis-cylinder upon the protoplasm of the series of mesoblastic cells which are wrapped round it.

Ranvier[34] and his pupil Vignal[35] compared the formation of the myelin to the formation of fat within a fat cell. Vignal's description of the process of myelination is as follows. At a particular stage of development, when the nerve-fibre consists of non-nucleated bundles of fibrils, mesoblastic cells migrate into the interior of the fibre and apply themselves closely to single groups. Their cell protoplasm increases in length and in breadth until some of the primitive fibrils are enclosed. The definite intervals in the enclosing sheath, corresponding to the nodes of Ranvier, coincide with the spaces between the ensheathing cells; consequently each internode represents a segment of the *continuous axis-cylinder* wrapped round by a mesoblastic cell. At the same time, according to Vignal, the myelin appears in the cell protoplasm in the form of minute droplets; these become more numerous and run together to form a general thin covering of the axis-cylinder. Vignal does not deny the possibility that the axoplasm may share in the formation of the myelin, but in quite a subordinate manner. The observations of Boveri, which recently have been confirmed by Bethe,[36] show that the sheath of Schwann is reflected inwards at the nodes along the axon; if this be true there is (as in a serous membrane) a parietal and central layer, and between the two the myelin is contained. This would prove Vignal's hypothesis. Gürwitsch has studied the development of peripheral nerves in embryo sheep, fixing the sciatic nerve with Apáthy's solution and employing various staining reagents used by that observer. He came to the conclusions: (1) that the nerve-fibre is a prolongation of the ganglion cell; (2) that the sheath of Schwann arises from the surrounding mesoblast; and (3) that the myelin sheath has nothing in common with the sheath of Schwann, and probably arises only as a product of the metabolism of axoplasm. Time will not allow me to give you more than

FIG. 3.

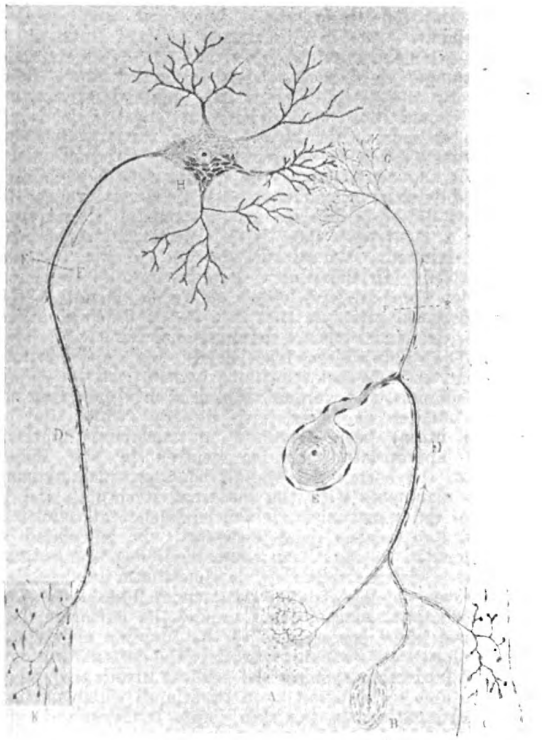

Diagram to show reflex arc. A, Skin with sensory endings. B, End organ, Pacinian corpuscle. C, End organ of tendon (Golgi). D, Sensory nerve fibre. (Only one sensory nerve fibre is represented as conveying impulses from the three above-mentioned structures, A B C, but it must be clearly understood that there are separate neurones for each.) E, Cell of posterior spinal ganglion with fine granules scattered through the body of the cell; these are the chromophil granules. Emerging from the capsule is the axis-cylinder process forming a T. The central process passes to the spinal cord; at F F the chain of tubular cells representing the sheath of Schwann ceases; but the axis-cylinder process is still covered with myelin; it breaks up at G into a terminal arborisation, which is in physiological connexion with H, the motor efferent neurone. The lower part of the cell is represented showing polygonal granules (Nissl); the upper part of the cell shows a fibrillary reticulum. The granules exist all over the cell and on the dendrons except at the emergence of the axis-cylinder process, but they are not represented in the upper part in order that the fibrillary reticulum of the achromatic substance may be clearly shown. The axon becomes coated with myelin; at F F it acquires a sheath of Schwann on emergence from the spinal cord and terminates at K in the motor end-plate.

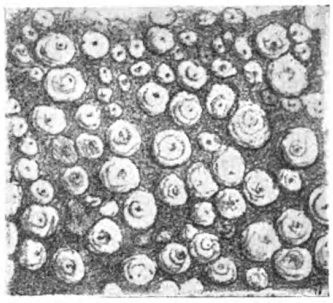
this very brief outline, and to those who are further interested in the subject I would refer them to an admirable digest on the Histology and Pathology of the Nerve-cell, by Ford Robertson,[37] or to the splendid new work of Barker on the Nervous System.

It would take too long here to describe the normal structure of the various forms of neurones, but to make myself more clear in speaking of degeneration and the changes which occur in the nerve-cell and its processes, I represent here diagramatically a spinal reflex arc, showing a sensory and motor neurone. (Fig. 3.) Each portion has a brief description appended, so that I need not detain you further with the details. I would call your attention, however, to two facts—viz., (1) the difference in the myelin sheath as it surrounds the axis-cylinder process and its fibrils within the spinal cord as compared with the myelin sheath outside the same—in the latter the axis-cylinder is surrounded by a chain of tubular cells containing the myelin, whereas in the former there is simply a continuous coating of the phosphoretted fat; and (2) the different arrangement and appearance of the stainable substance in the motor and sensory cell.

THE DEGENERATION OF THE NEURONE—BRIEF HISTORICAL INTRODUCTION.

New methods of experiment, observation, and technique mark the successive stages in our knowledge of the structure and functions of the nervous system in health and disease. 50 years ago Waller[38] gave his memorable communication to the Royal Society which was the commencement of our knowledge of the degeneration of the neurone. In his paper, "Experiments on the Section of the Glosso-pharyngeal and Hypoglossal Nerves of the Frog and Observations of the Alterations produced thereby in the Structure of their Primitive Fibres," he pointed out that Günther and Schön had ten years before stated that the primitive fibres at the end of a week after division of the nerve, and when it had lost its irritability, showed changes indicating degeneration; likewise Nasse and Steinrück had described changes following division of nerves. Waller's researches showed that a change took place throughout the whole of the nerve below the point of section, extending to its terminal fibrils. The diagrams exhibit the original pictures taken from Waller's monograph. (Figs. 4, 5, and 6.) He concludes his paper with this very apposite statement: "We cannot suppose that this is a local phenomenon and that the nerves do not participate in similar alterations, and that the brain itself, composed in great part of tubular fibres, must be excluded. It is impossible not to anticipate important results from the application of this inquiry to the different nerves of the animal system; but it is particularly in reference to nervous diseases that it will be most desirable to extend these researches." How much light the extension of these researches during the last 50 years has afforded to neurology can be best appreciated by reviewing the enormous strides which have been made in our knowledge of the anatomy, physiology, and pathology of the nervous system. Waller had anticipated that degenerative processes would be found to occur in the central nervous system, as in the peripheral nerves. He had not long to wait, for in 1852 Türck[39] published a paper showing secondary degeneration of the spinal cord after a transverse lesion, and in 1854 he published his classical paper on secondary degeneration of tracts in the spinal cord and their prolongations in the brain based upon 21 cases. As Waller's observations form the basis of our knowledge of secondary degeneration of the peripheral nervous system, so Türck's observations are the basis of our knowledge of secondary degeneration of the central nervous system. Waller in 1852 extended his researches and formulated the three following fundamental laws which are given in italics in an appendix to the work quoted. The appendix consists of 52 important statements bearing upon the results of his experiments.



"As a general rule the sensory fibres develop by starting from the peripheral and radical poles of the ganglion corpuscles and extend from these into the peripheral organs and in the spinal cord to a height undetermined."

"The ganglion corpuscle is in consequence the central organ for the formation and nutrition of its peripheral and central fibres and accordingly we shall call it the neurogenotrophic corpuscle and the ganglion the neurogenotrophic body."[40] [The neurone doctrine foreshadowed.—F. W. M.]

"Considering the ganglion in its simplest state as a bipolar corpuscle we are able to assert that every part of the radical and peripheral poles which is separated from the corpuscle disorganises, whilst the whole of the poles in connexion with the corpuscle remains normal."

Numerous observers since have claimed that the law formulated by Waller, that every part of a nerve which is separated from its cell of origin undergoes degeneration, *whilst the rest remains normal*, although fundamentally true, may require some modification; and the first observer whom I find to suggest this is Dr. W. H. Dickinson[41] who, in a very interesting paper on "The Changes in the Nervous System which follow the Amputation of Limbs," stated as a result of his observations that the posterior roots may atrophy, though still in connexion with the ganglia, and the anterior though still in connexion with the cord; and it appears that long disuse of a nerve is sufficient to lead to its atrophy, although those nervous structures which immediately regulate its nutrition are complete. (Diagrams here reproduced.) (Figs. 7 and 8.) Bérard in 1839 had

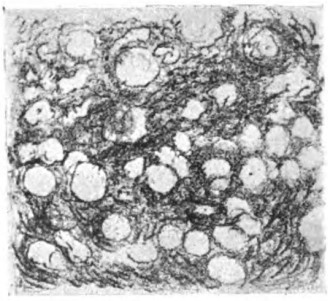


FIG. 7.

A transverse section of the normal sciatic nerve magnified 300 diameters. From an article by Dr. W. H. Dickinson published in the *Journal of Anatomy and Physiology*, November, 1868.

noticed atrophy of the central roots in a case of amputation. The degenerations described by Waller and Türck are degenerations *secondary* to injury and that described by

FIG. 8.

Dr. Dickinson and numerous other observers since may be looked upon as a *disuse atrophy*. A little later Gudden[42] commenced his celebrated work upon atrophy of the cells

of origin of a nucleus by tearing out the nerve in young animals, and this method threw great light upon the anatomy of the nervous system. It was adopted with striking success by Forel and von Monakow.

There is another form of degeneration which, accepting the cellular theory of Virchow [43]—that the whole organism, including the nervous system, is made up of an aggregation of cells, each cell being a living unit having an independent existence—is a *primary* degeneration of the complex nerve-cell or neurone. Every cell of the body nourishes itself and is not nourished—that is to say, every cell behaves as a unicellular organism possessing a specific energy; and by the vital reaction of its protoplasm upon the lymph environment metabolic exchanges, constructive and destructive, are continually taking place correlative with functional activity. We have no evidence to show that regeneration of nerve-cells can take place in the higher vertebrates, but there is some evidence in favour of the view that all the nerve-cells of the adult body are present in a rudimentary form at birth. The growth of the nervous system depends not so much upon an increase in number of the nervous units, but in their size by multiplication and complexity of the processes. Cajal (I reproduce his diagram) has shown that this growth in complexity during the process of development is not only true ontogenetically but also phylogenetically. (Fig. 9.) Wallerian degeneration proves that the nerve-cell is the trophic centre and the embryological researches of His have shown that it is the genetic centre. If then we admit the generally accepted view that the nerve-cell in the higher vertebrates is incapable of regeneration when destroyed, the corollary is that every nerve-cell of the human body is endowed with a specific durability whereby in the healthy perfect organism every neurone possesses an equally adjusted vital energy, so that not only is functional equilibrium maintained in the physiological processes of active life but also of decay, the regressive metamorphosis incidental to old age being manifested by a gradual and general enfeeblement of the functions of the whole nervous system. Lucretius says: "When the body has been shattered by the mastering weight of Time, and the frame has drooped, with its forces dulled, then the intellect halts, the tongue dotes, the mind gives way, all faculties fail and are found wanting at the same time. It naturally follows that the whole nature of the 'soul' is dissolved like smoke into the high air, since we see that it is begotten along with the body and grows up along with it, and as I have shown breaks down at the same time worn out with age." [44] In contradistinction to this normal senile decay are premature pathological processes of decay, attacking groups, systems, or communities of neurones subserving special functions, whereby functional equilibrium is destroyed, symptoms of disease are manifested, and according to the functional relations of the system selected characteristic symptoms are presented, constituting clinical groups. The neurones of a particular system die prematurely owing to an *inherited or acquired want of durability* and the regressive process of decay may be looked upon as a nutritional failure on the part of the same cells to maintain that metabolic equilibrium essential and correlative to functional activity; consequently, *those parts most remote from the trophic and genetic centre of the complex cell (neurone) degenerate.* The process may be regarded as the inverse of development, the fine collaterals and terminal arborisations being the first to disappear. Dr. Hughlings Jackson [45] in his Croonian lectures, March, 1884, states: "I have long thought that we should be very much helped in our investigation of diseases of the nervous system, by considering them as reversals of evolution, that is, as dissolutions." Morphologically I conceive that the process of primary degeneration is an evolutional reversal commencing in the structures latest developed, namely, the myelin sheath and the terminal arborisations and collaterals of the neurone.

FIG. 9.

A transverse section of the cervical part of the spinal cord from a man whose left arm had been amputated 23 years before death. The left posterior column (L) is smaller than the right. From an article by Dr. W. H. Dickinson, published in the *Journal of Anatomy and Physiology*, November, 1868. Two circular darker patches in the white matter are accidental imperfections in the picture.

Before entering into a detailed account of my own observations upon the degeneration of the neurone, which will occupy most of the other three lectures, I will give a few illustrations relating to the neurone theory as regards the transmission of impulses and certain physiological problems connected with variable resistance to transmission and the spread of excitation.

EVERY POINT OF THE CENTRAL NERVOUS SYSTEM IS IN PHYSIOLOGICAL, IF NOT IN ANATOMICAL, CONNEXION WITH EVERY OTHER POINT, AND RESISTANCE TO THE SPREAD OF EXCITATION IS VARIABLE.

The nervous system may be said to consist of three systems of neurones—afferent, efferent, and association systems (*vide* diagram). (Fig. 10.) Every excitation can spread over the whole nervous system, but it is difficult to understand how there may be a variable resistance to the spread of an excitation, if we accept the diffuse

[43] Cellular Pathology.

[45] Post-Epileptic States, Journal of Mental Science, October, 1888.

continuous network theory of Gerlach or of Golgi, or how use may lead to the opening up of paths so that the time occupied by transmission of impulses may be diminished by repetition. Facts seem to show that there is a delay in the transmission of impulses in the passage from one neurone to another in the central nervous system. Does this delay occur at the junction of the terminal arborisations at the axon of one neurone with

FIG. 10.

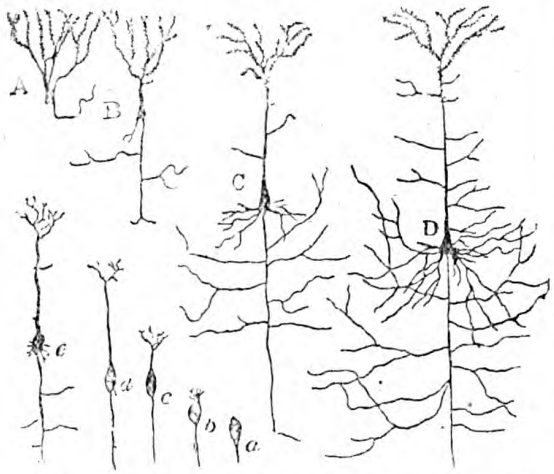

Diagram after Ramòn y Cajal to show the ontogenetic and phylogenetic development of a psycho-motor neurone. A, Frog. B, Newt. C, Mouse. D, Man. It will be noticed that as the zoological series rises there is an increase in complexity of the neurone and in the multitude of points of contact produced by an increase in the dendrons and side-branches of the axon. *a*, *b*, *c*, *d*, *e*, show ontogenetic development of a psycho-motor cell in the human embryo. The reversal of this process takes place in primary degeneration.

the dendrons of another? or does the resistance occur in the protoplasm of the cell body?

Bubnoff and Heidenhain found that the strength of stimulus was related to rate of transmission *in the central nervous system*, for on stimulation of the cerebral cortex of the dog, the reaction time is shortened by increase in the strength of the stimulus; whereas *the peripheral nerves* are influenced as regards rate of conduction only to a comparatively trifling degree by the same increase of stimulus.

It would therefore appear that a stimulus passes from the upper neurone to the lower more rapidly when the stimulus is strong than when weak, that is to say, the excitation in the upper neurone must reach a certain intensity before it is capable of flowing over and exciting the next in the series. Is the resistance to the passage of the impulses in the physiological junction of the upper and lower neurones, or in the protoplasm of the cell-body? According to the neurone theory it would be at the junction.

A stimulus which is insufficient to rise into consciousness may, by repetition, lead to summation, and the opening up of a path (*Bahnung*) by breaking down resistance; thus Urbantschitch has shown that very weak sounds, at first not audible, become so by repetition. This effect can be explained by the stimulus opening up the path to the auditory perceptive centre. The same effect can be produced by an effort of the will and concentration of attention, by which the auditory perceptive centre becomes more excitable. That an excitation may spread over the whole nervous system is not to be wondered at when we consider the length of some of the projection system neurones; for example, the posterior spinal sensory neurones, which have their cells of origin in the first sacral ganglion, extend from the nape of the neck to the sole of the foot. The central projection of the T-shaped process gives off a branch, which extends in the column of Goll the whole length of the spinal axis, and the peripheral portion as a sensory fibre extends to the sole of the foot. It is probable, therefore, that the central projection establishes connexions by delicate collaterals with the grey matter of the whole spinal axis. The reason why excitations do not spread is probably dependent upon the condition of the bio-chemical stability of the neurones. In strychnia and tetanus poisoning the most localised peripheral excitation will cause general muscular spasm; in both toxic conditions the spread is probably due to a bio-chemical change in the protoplasm of the spinal motor neurones to be referred to later, whereby the excitability is greatly increased, and a slight impulse is sufficient to fulminate the whole system of motor neurones. In epilepsy and other paroxysmal neuroses and psychoses it is possible that some altered condition of the blood associated with an inherited bio-chemical instability of certain groups, systems, or communities of neurones may act as *a fulminating agent*. In neuralgia and local hyperæsthesia the slightest general or distant local irritation suffices to produce pain; thus coughing, the vibration of a passing train, or a slamming door may produce pain by the stimulation of the hyper-excitable neurones.

If a skin reflex is increased on one side of the body then sometimes a slight excitation on the normal side is sufficient to produce the crossed reflex, while perhaps the excitation is not sufficient to bring about the normal reflex on the sound side. It sometimes occurs that associated sensations (in part of a painful nature) arise from pressure upon spots, which cannot be explained upon any known anatomical basis. This condition can be understood only by supposing that certain groups of neurones are in a state of hyper-excitability, and that the neurones which are stimulated have fortuitously opened up the connexion by association neurones and it has been fixed and made easier by each successive stimulation. The excitation spreads, but it is not of sufficient intensity to arise into consciousness, except in the hyper-excitable area.[46]

Besides hyper-excitability, there may be diminished excitability affecting groups, communities, and systems of neurones having special functions. It will be seen later that this lowered excitability is usually the result of the selective action of various poisons producing either functional depression or degeneration, whereby paralytic or other symptoms of loss of function arise in certain definite functionally related systems of neurones, thus causing correlative groups of clinical symptoms due, on the one hand, to perverted function, or loss of function, and on the other hand producing other groups of symptoms, as pointed out by Hughlings Jackson to be "due to over-activity of nervous arrangements which are perfectly healthy." This disturbance of the functional equilibration of the neurones may be studied by a consideration of the nervous mechanism concerned in voluntary movement. The diagram shows (Fig. 11) that three nervous circles, spinal, cerebral, and cerebellar, are engaged and all three systems of neurones take part, for in every voluntary movement impulses are passing up the afferent channels and down the efferent, and these two systems are brought into physiological harmony by the association systems.

DISTURBANCE OF THE FUNCTIONAL EQUILIBRATION OF THE NEURONES.

The perfection of a voluntary movement is brought about by the association and equable adjustment of systems and communities of neurones presiding over groups of correlated antagonistic muscles in such a way that the desired movement is produced with the least expenditure of nervous and muscular energy. Interference with the functions of any one system will disturb the normal functional equilibration that must of necessity exist in the action of the whole. Dr. Hughlings Jackson emphasises the fact that the symptoms of nervous disease are due as much to normal physiological functional activity imperfectly applied as to the actual loss of function occasioned by the disease. He pointed out that in paralysis of the external rectus, strabismus caused less trouble to the patient than the double vision occasioned by the physiological activity of the two retinæ upon which the images were prevented by the paralysis from falling upon corresponding points. Again, the importance of the integrity of one set of neurones having a specific function upon all the rest of the functionally related neurones was strikingly shown in some experiments by Sherrington and myself,[47] for we found that if the upper limb were rendered *apæsthete* by section of a number

[46] Goldscheider: Die Bedeutung der Reize für Pathologie und Therapie im Lichte der Neuronlehre, 1898.

[47] Experiments upon the Influence of Sensory Nerves upon Movement and Nutrition of the Limbs. Proceedings of the Royal Society, 1895, vol. lvii.

of the posterior roots (third cervical to third dorsal inclusive) not only was the limb of the animal rendered insensitive, but it was unable to perform the finer voluntary movements; although stimulation of the cerebral cortex in appropriate regions produced every movement, showing that the efferent path for voluntary movement was still open, but the animal

FIG. 11.

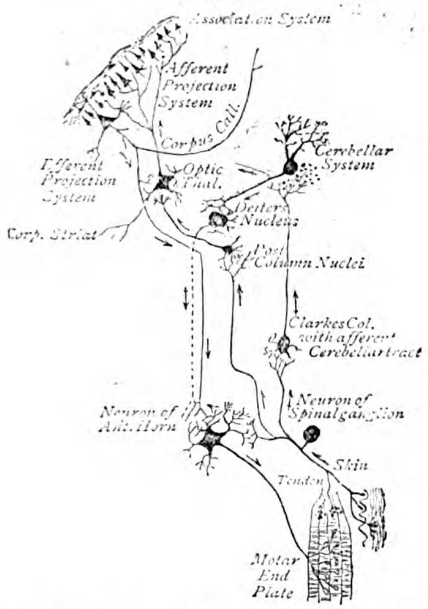

Diagram to show the three systems of neurones, illustrating the path of sensory impulses to the cerebrum and cerebellum, the path of outgoing impulses from the brain in a voluntary movement and the association of the afferent and efferent projection systems in the grey matter of the brain. This diagram also illustrates the path of a simple spinal reflex and of a psychical reflex.

was unable to *ideate* the movement. Another marked effect of section of the posterior roots was the immediate loss of tonus in the muscles, showing that peripheral stimulation is the important reflex agent in its production.

Again, the experiments of Bubnoff and Heidenhain[48] show the intimate relation which exists between the functionally related neurones. They found that a weaker stimulus was required to produce a movement of the limb by faradaisation of the cortex cerebri if the limb were gently stimulated; thus showing that not only in a movement do impulses pass from the cortex to the periphery, but that each successive movement and alteration in tension of the skin, muscles, tendons, and articular ligaments causes a transmission of *kinæsthetic* impulses (Bastian) from the periphery to the cortical centre with an increase of its excitability; thus there is a continuous molecular vibration occurring in all these circles, and this is of importance with regard to the metabolic exchange and nutrition of the neurones themselves; for stimulus is essential to function and bio-chemical action.

In discussing later the changes which occur in motor nerve-cells when their axons are cut we shall better appreciate the changes which take place by remembering that if a muscle is paralysed changes in tension of the related structures—namely, muscle, tendon, skin, ligaments, &c.—cannot occur, and that normal succession of kinæsthetic stimuli which travel up the afferent system *pari passu* with the stimuli that travel down the efferent no longer take place. Warrington,[49] indeed, has shown that section of posterior roots causes chromolytic changes in the anterior horn cells of the same side, indicating that this loss of stimulus produces a depression of the metabolic functions of the spinal motor cells, a fact quite in accord with the physiological results above described.

ANATOMICAL CORRELATION OF ASSOCIATED SYSTEMS OF NEURONES.

The correlation of associated functionally related systems, groups, and communities of neurones finds an anatomical proof in regressive associated atrophy of correlated structures. A good instance of this has lately been investigated in my laboratory by Mr. Tredgold. Cases have previously been published of a similar nature, but there are some points in this case which have not previously been noticed. The patient suffered from right congenital hemiplegia affecting especially the hand and foot. The lesion was primary in the optic thalamus of the left side; it caused atrophy of the left hemisphere, the right half of the cerebellum, and the spinal motor neurones of the cervical and lumbar enlargements, descending degeneration of the right crossed pyramidal tract, and of the left antero-lateral tract. We thus see, referring to the diagram, that all the functionally associated efferent tracts of the three nervous circles engaged in voluntary movement had undergone atrophy in consequence of the disuse occasioned by the primary lesion preventing the development of that normal association of correlated neurones necessary for perfect voluntary movement. There are certain very interesting points in this case which will be fully published in the next number of *Brain*.

DIFFERENTIATION IN DIABETES.

BY F. W. PAVY, M.D. LOND., LL.D. GLASG., F.R.S.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

(*Continued from p. 1708.*)

THE "ALIMENTARY" FORM OF DIABETES.

A FAULTY power connected with the application of the carbohydrate matter of the food within the system constitutes the essential condition that we have to deal with in this form of diabetes. As a broad fact it is noticeable that when the carbohydrate principles of food are ingested by a healthy person nothing is seen of them afterwards and all that is observed is the general benefit that follows. The system possesses the power of placing them in a position to pass in the direction of utilisation. Neither in the blood of the general circulation nor in the urine do we find evidence given of their ingestion. A certain small standard amount of sugar is met with in both the blood and the urine, and this is not influenced by the presence or the absence of carbohydrate matter in the food. Not so, however, in the case of diabetes. Here the carbohydrate matter of the food finds its way in the form of sugar into the blood and thence into the urine. Failing to be assimilated, or placed in a position to be properly disposed of, it improperly reaches the general circulation as sugar, and this in its transit through the kidney runs off as waste material with the urine.

If by the exercise of assimilative power sugar is prevented from reaching the general circulation it cannot reach the urine. But the assimilative power is not in anyone found to be of unlimited capacity; and in the healthy subject sugar may appear in the urine as the result of an excessive ingestion of carbohydrate matter, especially if it be taken in the soluble form—for instance, as sugar—and at a period of fasting. When the assimilative power falls short of what is natural the amount of carbohydrate food that can be taken by a healthy person without giving rise to the escape of sugar can no longer do so without producing glycosuria, and in proportion as the power is reduced so is the curtailment in the amount of carbohydrate that can be taken without influencing the urine. Very varying degrees of impairment of the power are found to exist in different cases, producing varying degrees of severity of the complaint. This requires to be taken into account in treatment in order that a properly adjusted diet may be supplied to meet the particular demands of the case that is being dealt with. For the adoption, therefore, of a rational mode of procedure it is necessary that differentiation should be extended and carried into the group of cases that is now receiving attention.

We no longer hear of excessive secretion of sugar by the liver being talked of as the explanatory factor of diabetes. It is now generally accepted by those abreast of recent knowledge that things stand in a different position from what was

formerly taught. The phenomena of diabetes, as I have for a great number of years strenuously urged, stand in antagonism to the view that the carbohydrate of our food undergoes a functional transit in the form of sugar through the general circulation from the seat of ingestion to that of utilisation in the tissues. Everything points to the carbohydrate matter belonging to our food passing as sugar into the general circulation in diabetes in a manner that does not occur in health, and our language is shaped accordingly. We speak of its undergoing under natural circumstances a process of assimilation; and, in diabetes, of the failure of the proper performance of this process as leading to the result observed.

The object of assimilation is to put into a suitable state for contributing to utilisation. We know that animals are fat-producers from carbohydrates. No question now exists as to this. I have given grounds[1] for locating the chief seat of this process in the intestinal villi, the fat produced passing, like the ready formed fat that has been ingested, through the lacteals into the circulation. This is one method of the disposal of carbohydrate. I have also at the same time pointed[2] to its disposal by synthesis with nitrogenous matter into proteid, and my views, I think it may now be said, have been accepted by physiologists. Provision is thus made for the transit of carbohydrate within the circulation without passing into the urine. As a small-sized molecule, like that of sugar, there is nothing to prevent its escaping into the urine in the same manner as other small-sized molecular, and therefore diffusible, substances, whilst traversing the vessels of the kidney. It may rationally be taken that the size of the molecule constitutes an all-important point in relation to the question of elimination with the urine, and sugar locked up in a large-sized proteid molecule will not be placed in a suitable position for escaping, whilst in a free state it will. The investigations of the last few years on the relation between nitrogen and sugar elimination in phloridzin and pancreatic diabetes in the unfed animal, in which the tissues of necessity are the source of the sugar, show that there must be a very significant amount of carbohydrate entering into the constitution of a proteid molecule.

The recognition of the "*alimentary*" form of diabetes is effected, not only by the elimination of sugar being susceptible of control by the exclusion of carbohydrate matter from the food, but also by the absence of the products, diacetic and oxybutyric acids, of tissue breaking down, to which allusion has previously been made. If the ferric chloride test gives no reaction it may be taken that thus far the case is only in the "*alimentary*" form. It is fortunate for diagnostic purposes that the information can be so easily obtained. Corroborative evidence is afforded by comparing the results obtained by estimation of the sugar by cupric oxide reduction and the polarimeter; but, as has been mentioned, although it is compatible for diacetic acid to be present and oxybutyric acid to be absent the converse is not found to occur, from which it follows that an absence of diacetic acid implies also the absence of oxybutyric acid.

To ascertain the degree of severity of the condition existing in an "*alimentary*" case the food test must be employed. It may happen that the loss of assimilative power is such that even with a properly constructed restricted diet the carbohydrate contained in it (it is not possible to construct an existence diet entirely free from carbohydrate) suffices to throw a certain amount of sugar into the urine, but ordinarily the loss does not amount to this, and then under the restricted diet, rigorously followed, a sugar-free state of urine is secured. With a less degree of loss a certain amount of carbohydrate food is tolerated in conjunction with the restricted diet without leading to the passage of sugar; and so it runs on, more and more carbohydrate being tolerated in proportion as there is less and less loss of assimilative power, until the condition is presented in which it is only when an exceptionally large amount of carbohydrate has been taken that sugar is found in the urine. Such a condition is often the source of considerable perplexity on account of the irregularity as regards presence and absence of sugar noticeable in the state of the urine.

Having determined in a particular case the amount of carbohydrate tolerated the foundation is supplied for adjusting the diet rationally to meet the requirements. What is wanted is to keep the urine free from sugar and whilst doing this to allow as much carbohydrate as the circumstances permit. The medical practitioner has to feel his way, and this is best done by conjoining with the restricted diet a weighed amount of ordinary wheaten bread, which is the article most missed by the diabetic and most easily supplied in regular amount. It may be that only three ounces per diem, in one-ounce portions at each of the three principal meals, are found to be susceptible of being taken without leading to the passage of sugar. It may be four and a half, six, seven and a half, or nine ounces or more that are tolerated. Whatever the amount the conclusion may be drawn through its not running off as sugar in the urine that it falls within the assimilative power existing and thus stands in a position to go to the benefit of the system. Carbohydrate food that fails to be assimilated and is discharged as waste material with the urine cannot be of service to the economy; it is, indeed, pernicious on account of its passage as sugar through the circulation producing a deviation from the natural state. The larger the amount of sugar permitted to reach the general circulation and flow off with the urine the greater will be the abnormality existing and the more pronounced the various troubles occurring.

I have spoken of an allowance of bread as best suited to be given when it is desired to conjoin a certain amount of carbohydrate food with the restricted dietary, but if the quantity could be properly estimated the equivalent of starchy matter in any other article might be substituted. There is no scientific foundation for considering that the starchy matter of one article behaves in a different way from that of another. Between starch and the sugars, however, a difference exists inasmuch as the latter being soluble and diffusible, and therefore ready for immediate absorption, will enter the system with a rapidity not occurring with the former, which has to undergo transformation into sugar by the digestive secretions before absorption can take place. In cases where a considerable quantity of carbohydrate is tolerated it may be desirable to allow a portion of it to be drawn from other articles than bread. If this liberty is given in order to secure that the tolerating capacity is not overstepped a margin of assimilative power should be allowed to exist—in other words, the liberty allowed should stand well within that which will lead to the appearance of sugar in the urine.

We look to the urine for affording the means of ascertaining when the carbohydrate given surpasses the assimilative power existing, but it does not tell us when the carbohydrate is being unnecessarily curtailed. This we learn in another way. It is an interesting fact that the body weight in the following manner supplies the desired knowledge. When there is no toleration of carbohydrate food the restricted diet does not lead to loss of weight. Indeed, when the patient is first put upon it, after having sustained more or less loss before the commencement of treatment, the weight rises, sometimes to a marked extent, and is subsequently maintained. This subsequent maintenance of weight refers to the cases of the "*alimentary*" class in which the restricted diet is necessary for keeping the urine free from sugar. In such cases I have known patients go on for years fully maintaining their weight. On the other hand, should the case be one of a mild nature—one in which starchy food to some extent is tolerated—the restricted diet leads to a fall in weight. Loss of weight on the restricted diet with sugar-free urine may be read as meaning that an unnecessary amount of restriction is being practised, and when the starchy food is given, for the disposal of which sufficient assimilative power exists, the weight immediately rises.

When a restoration of assimilative power occurs in the course of treatment a loss of weight, upon the same principle, sets in unless the condition is met by a properly adjusted supply of carbohydrates. Restoration of assimilative power is the true *desideratum* of treatment and it often happens with persons above middle age that it is to a greater or less extent attainable. At first in these cases there is nothing special observable. The urine more or less quickly loses its sugar and the ordinary improvement in the weight and the general condition of the patient occurs. Later—it may be after the lapse of some weeks but more frequently of a few months—a loss of weight sometimes rather sharply sets in, with possibly a return of the feeling of weakness that was experienced at the commencement, which not unnaturally leads the patient to think that a relapse has occurred. With sugar-free urine, however, these phenomena, instead of being of bad augury, are really a good sign: they are indicative of returning assimilative power. As long as the assimilative power does not exist carbohydrate food

[1] Physiology of the Carbohydrates, 18 p. 248.
[2] Ibid., p. 241.

cannot be wanted by the system. As soon, however, as the power becomes restored the want springs up and unless it is met the described phenomena occur. I cannot penetrate the depths of metabolism and say why this should be, but it may be stated that it represents a return to the position belonging to health. We know that if a healthy person is deprived of carbohydrate food a loss of weight ensues. With the restoration of the absent assimilative power met with in the diabetic we have a retrocession to the natural state, and as the natural state in this respect is regained, so do the co-existing circumstances fall in with it. It is only gradually that the power is restored, and the case requires to be dealt with accordingly. A limited amount only of carbohydrate should be given at first. A large amount would to a certainty bring back sugar. The effect of the carbohydrate is to check the loss of weight and otherwise afford relief. Later there may be a recurrence of the phenomena, and this requires to be met by an advance in the allowance of carbohydrate food. Thus the case may progress until possibly, but not generally, the tolerance of about, or even actually, an ordinary diet is re-established.

The food test is often required to be applied for diagnostic purposes. It may also be turned to account in life insurance cases. In August, 1898, a patient came to me with an indefinite history of diabetes. He was not dieting and only sometimes had sugar been found. The urine passed for my examination at 10 A.M. was free from sugar. The patient went away and partook, at my suggestion, of greengages, sponge-cakes, and lemonade. The urine passed on his return three and a half hours afterwards contained 55·5 per 1000 of sugar.

In April, 1899, my opinion was sought in connexion with a life insurance case. The proposer's urine had for some time been occasionally found to contain sugar. He had been examined by a number of medical men and doubt existed with regard to his state. No dieting had been resorted to. The urine passed at the time of his visit to me contained no sugar. He partook in my house, at my request, of marmalade and bread and butter. This was at 1 P.M. He had a train to catch at 3 and at 2.35 he returned and passed urine which was found by copper reduction to contain 30·8 per 1000 of sugar. The existence of the sugar was confirmed by the polarimeter and the osazone test. In another similar life insurance case the amount of sugar found two and a half hours after the application of the food-test was 8 per 1000.

Any number of examples illustrative of the immediate effect of carbohydrate food on the urine in the diabetic might be brought forward and it represents the great point of contrast with the condition belonging to health. The contrast existing has an underlying significance in relation to the question of whether the carbohydrate of our food normally reaches the general circulation as sugar or not. If it is assimilated and thus disposed of before the general circulation is reached the opportunity is not afforded for its reaching the urine. If not so disposed of some other course of events must ensue and its appearance in the urine as sugar affords an indication of what must have happened. Failing to be properly arrested by assimilative action it passes as sugar into the general circulation where such sugar is to be recognised as distinctly as in the urine.

Everything contributes to show that in diabetes the fault lies with sugar being wrongly permitted to reach the general circulation as a sequence of the non-assimilation of the carbohydrate matter ingested, and not with failure of the disposal of sugar within the circulation under the assumption that it is normally fated to arrive there. The experimental introduction of sugar into the circulation by intravenous and subcutaneous injection affords us help in unravelling this matter and renders it manifest that our carbohydrate food could not reach the general circulation as sugar without the fact being revealed through the medium of the urine. I may refer to an extensive series of experiments recently undertaken by me and published in the *Journal of Physiology* for last year, from which it is seen that sugar, even in as small a quantity as the four-thousandth part of the weight of the animal, cannot be directly introduced into the circulation without exerting an influence upon the urine, and a certain amount of time is required for its disappearance from the blood to be effected. Looking at the quantity of sugar that reaches the urine from carbohydrate food in diabetes it is impossible, in view of the facts before us, to conceive that such could reach the general circulation in the normal state and escape showing itself in the urine. Evidence tells us that the system generally is not devoid of assimilative power over sugar after its arrival in the general circulation, but the power is altogether short of that which would be needed in this way to account for the disposal of the carbohydrate matter of our food, and especially without leading to implication of the urine. Disposed of by transformation into fat and synthesis into proteid before the opportunity is afforded for the general circulation to be reached conditions are supplied that harmonise with all the requirements of existing circumstances. Carbohydrate incorporated within the proteid molecule is in a position to be secure against exit with the urine. It can in this state exist in the circulation without escaping as waste material in its passage through the kidney and subsequently be applied wherever it is needed. In the "*composite*" form of diabetes it is abnormally set free from this combination and thence finds its way as sugar into the urine.

(*To be continued.*)

SOME NOTES ON THE INTRODUCTION AND SPREAD OF PLAGUE.

BY G. J. BLACKMORE, M.B., C.M. EDIN.,
LATE SPECIAL PLAGUE MEDICAL OFFICER, BOMBAY AND CALCUTTA.

THE gradual extension of plague over the world and its reappearance in Egypt bring home to us with great force the fact that this dread disease is knocking at our very doors and may soon effect an entrance unless we are constantly on the alert to prevent it. It seems, therefore, to be an opportune time to draw attention to some of the known facts about its spread and to make one or two suggestions with a view to preventing its introduction into this country.

It will be as well first to describe the course taken by plague when it attacks a place for the first time and then to consider the course taken by it later when it has assumed an epidemic form, because it has to be borne in mind that plague seldom starts as an epidemic but almost invariably as a few isolated cases which do not tend to spread to any extent and which soon disappear. In Bombay the disease was not recognised until it had practically become epidemic, but it is certain from information that has since been obtained that sporadic cases had been occurring in the city for some considerable time before the first case was reported. In Calcutta, on the other hand, it is probable that the very earliest cases were discovered immediately they occurred, as the health authorities had been constantly on the watch for the disease owing to its presence in Bombay. We have, therefore, had the opportunity in Calcutta of watching the progress of the disease from its commencement until now, when it has become epidemic.

The Calcutta experience has shown—and it is being confirmed elsewhere—that during the first year only a few cases occur. These are generally not of a very severe character, and in a short time the disease apparently disappears. The following year, however, it appears again about the same time as it originally made its appearance. Now, however, there are many more cases, the disease is distinctly more virulent and lasts longer, but can scarcely yet be said to be truly epidemic in character. Once more the disease appears almost to die out, but only to reappear in the next year as an epidemic, and we are now able to note the course pursued by an epidemic visitation. This course is shown very clearly in the chart published by Dr. T. Frederick Pearse in THE LANCET of May 5th, p. 1274. Starting about the time of the original appearance of the disease, at first few cases occur and the numbers increase slowly for some little time; then there is a sudden and swift rise—week by week the numbers mount higher until in about nine or ten weeks from the first definite rise they reach their maximum. For four or five weeks the numbers remain high, but fluctuate somewhat; then the decline sets in and the numbers fall rapidly for some weeks, until at last there is a gradual tailing-off to complete, or almost complete, extinction of the disease. The whole cycle in Bombay of the plague in its epidemic form occupies about six or seven months. During the remaining months of the year the disease appears to be slowly gathering strength for a

fresh and more virulent onslaught. Whether the limit of virulence has yet been reached it is impossible to say, as up to the present the sad experience of Bombay and Poona has only shown that each visitation has been more virulent than those preceding it.

Having described the course of a plague outbreak—and the bearing of this on the prevention of its spread will be seen later—a few words may be said about the means by which plague is passed from person to person and from place to place. Unfortunately, in spite of all efforts to discover it, the means by which plague is communicated from one person to another has not yet been discovered. We do not know how the sick infect the healthy. It appears improbable, however, that much, if any, infection takes place through the air or that mere contact with infected persons is sufficient to cause the disease, as it is rare for attendants on the sick to contract plague. It is very probable that the process is one of inoculation, either through wounds or abrasions, or, what is far more probable, by means of insects, especially fleas. It has been shown by Simon that fleas found on plague-infected rats contained the plague bacillus and it was proved by experiment that such fleas could convey the disease to other rats; and although it has been denied that the fleas which infest rats will bite human beings, it is only reasonable to suppose that the species which do bite human beings are as capable of conveying the disease from a diseased person to a healthy person as the flea of the rat is of conveying it from a diseased rat to a healthy one. It is, in fact, judging by clinical experience, extremely probable that vermin play an active part in passing plague on from person to person.

Of the means by which plague is conveyed from place to place we know very little more than we do about its passage from person to person. It can, of course, be carried by an individual who is already suffering from the disease; other modes of conveyance are more or less conjectural. A certain number of cases have been traced to the importation of rags and dirty clothing from infected localities, and in other cases it is assumed that rats have carried the disease. While it is probably true that diseased rats in one place have been the means of conveying the plague to healthy rats in another it has not yet been shown that rats play an important part in spreading the disease among human beings. In many places a great mortality has been observed among rats prior to the appearance of plague among the inhabitants, but such mortality has not always been followed by plague among human beings. It is possible that both rats and human beings are infected from the same unknown source, but as rats are much more susceptible to the disease than man is we should naturally expect that if both were infected from the same source the rats would first show evidence of the infection, while in a certain number of cases they would be infected and human beings would escape. Inasmuch, however, as the disease found in rats is undoubtedly identical with that which occurs in man, and as in a few cases proof has been forthcoming that persons have contracted plague from the bites of rats, these rodents must be considered to be a source of great danger. It is unnecessary to consider here the other animals which may contract, and be a possible means of disseminating, plague, as Dr. F. G. Clemow[1] has lately published full and instructive notes on this point, and as rats are the only animals with which we are likely to be immediately concerned.

I may now pass on to suggest some of the means to be adopted in trying to prevent the introduction and spread of plague, and must premise my remarks by saying that when once plague has become epidemic in a country we know as yet of no means of absolutely stamping it out. Every effort therefore should be made to prevent the disease from getting a footing in this country, as, once in, we shall have the greatest difficulty in getting it out again.

A recent writer has said that "there is no mystery about plague. It can be stamped out like any other infectious disease or like a pest of locusts or black beetles." Such a statement is justified neither by the present condition of things in Egypt nor by past experience of plague in other countries. Statements of this nature are calculated to do harm by engendering in the public and the profession a false sense of security and by leading them to believe that a few cases of plague occurring in a country are of no particular consequence as they can easily be stamped out by sanitary measures. It is because sanitary measures have hitherto generally failed to effect this desirable result that I lay such stress on our using every means in our power to prevent the introduction of the disease.

The measures to be adopted in preventing the spread of plague may be considered under two heads: first, those adopted by the country in which plague has appeared, to prevent the disease from passing out of the country by sea or by land; and secondly, the measures adopted by threatened countries to prevent the disease from gaining ingress. The Venice Convention has provided for the first, and it is unnecessary to say much about it, excepting on one point and that a very important one. Although provision is made for attempting to prevent the egress of plague while the disease is actually in a country, it cannot be too strongly urged that the danger of exporting the disease is not over when it has apparently been stamped out. Too little attention has been paid to this fact. I have already shown that a period of quiescence always follows an outbreak of plague and is especially marked while the disease is yet new to the country, may indeed be so marked that the plague appears to have ceased to exist in the community. But the belief that plague has died out with the last reported case does not appear to be founded on fact. When once the disease has attacked a place it has been abundantly proved that the same place is liable to be attacked again, and generally is so attacked within the next 12 months. From personal experience and from statements made to me by many capable native medical men in Bombay I am strongly inclined to believe that during the whole time between the dying out of plague in one year and its reappearance in the next the disease is really present among the community in a mild form. In 1898 and 1899, during the time when plague was supposed to be almost absent from Bombay considerable numbers of people suffered and recovered from a disease which there is little doubt was plague in a modified form, but which was not reported as such. The disease at this time was of such a mild nature that most of the characteristic features were absent; it appeared to be passing through a phase when it was gathering strength for a fresh attack, and the cases did indeed become gradually more virulent until they apparently led up to, and became merged in, a fresh outbreak of plague. This modified form may easily be overlooked, especially where simple fever is so common as it is in tropical countries, nevertheless plague is capable of being carried from place to place in this form, and of afterwards passing into the most virulent form of the disease. This probably accounts for the many unexplained outbreaks of the disease in widely separated places where no possible source of infection could be found. The great danger of this form of plague is not only that it easily escapes detection at its place of origin, but that it may give rise in a new community to a disease of such a mild and unsuspicious nature at first that it may have spread considerably and to distant parts of the country before it is recognised. Inquiry has shown that this is not purely an assumption, but that cases of this nature have undoubtedly occurred in India. No place, then, in which plague has occurred should be considered to be absolutely free from infection until 12 months after the outbreak, and suspicious cases should be carefully looked for during that time.

Some of the preventive measures to be adopted by a country threatened with a visitation of plague may now be considered. Most of these are obvious by what has been said about the various modes of disseminating plague. It is imperative, in the first place, that the strictest examination should be made of all vessels and all passengers coming from infected areas, and in this connexion it is necessary to say that we must have the cordial coöperation of the people if our efforts to prevent the introduction of the disease are to prove successful. All persons who come from places where plague is present, or is suspected of being present, should consider themselves possible sources of infection and should not treat even an apparently slight indisposition lightly for at least 10 days after leaving a vessel which has been in an infected port. It is only with the help of such persons that the first cases of plague will be discovered, and it is only by discovering the very first cases that the pestilence will be prevented from spreading and the country saved from this devastating disease.

The second point to which great attention should be paid is the mortality among rats in seaport towns. Not so much with a view to increasing this mortality as because in rats

[1] Brit. Med. Jour., May 12th and 19th.

we have the most valuable known indicator of the approach of plague. If, however, an organised attempt is to be made to destroy the rats in this country, but more especially in seaports, it should be made now; it will probably be useless when the plague has appeared among human beings. It is because rats generally show that plague is present among them before it has appeared among the inhabitants of the same place that, until such time as the rats are exterminated, if they are to be exterminated, a close watch should be kept on their movements and their death-rate in seaport towns, and some of those found dead should be regularly submitted to bacteriological examination. An increase in the rat mortality is a very plain danger signal to which we should pay prompt attention. If the plague bacillus is found in rats submitted for examination persons in the vicinity of the place where such rats were found should be urged to submit to inoculation as a prophylactic measure, and all medical men should be warned to be on the look-out for cases of the disease.

A crusade which it is quite as necessary should be instituted as the crusade against rats is that against vermin —fleas and bugs particularly. As I have already stated there is good reason for believing that fleas convey the plague from diseased persons to healthy persons and may act as carriers between the rat and man. Fortunately the majority of English persons have an instinctive aversion to vermin of any kind and try to keep their homes and persons clear of them, apart from the question as to whether they convey disease or not. But it is quite a different matter in the case of the slum-dwellers. Everyone who is acquainted with the slums in any of our cities knows that they simply swarm with vermin. Our sanitary measures have not touched this evil. We may provide people with pure water, unadulterated food, and good drains, but no sanitary measure, no Act of Parliament, will ensure personal cleanliness. We pride ourselves as a nation on our personal cleanliness. The slum-dweller in these islands is no cleaner than our ancestors were when the Great Plague swept over the country. Nor can we expect much improvement in this respect so long as the terrible overcrowding which is so prevalent in the slums is allowed to continue. This lack of personal cleanliness and this overcrowding constitute a danger of the gravest nature in view of the threatened invasion of plague. It should be made widely known that the extermination of vermin is an important factor in the prevention of the introduction and spread of plague.

The only other point to which I wish to draw attention is the disinfection of rags and dirty clothing coming from infected places. The undoubted danger existing in dirty clothes which have been in a plague-infected house is probably due rather to the vermin so often present in them than to the dirt in which the bacillus is supposed to be present, and for this reason the authorities should see to it that dirty clothing and rags from infected places are not imported into this country until they have been acted on in such a manner that not only all bacilli, but also all vermin, have been killed.

The conclusions to be drawn from these remarks are that if plague is to be prevented from entering this country there must be (1) a most careful search made for modified cases of plague for some considerable time after the disease has apparently died out in places that have been attacked by it; (2) rigid inspection of vessels and passengers coming from infected places, not only while they are known to be infected but for months afterwards; (3) disinfection of dirty clothing and rags coming from such places; (4) a sharp look-out kept for any increased mortality among rats in seaport towns, with repeated search for the plague bacillus in the bodies of those found dead; (5) an attempt made to exterminate the vermin which may act as carriers of the plague; and (6) early inoculation of the people when plague has appeared among rats.

Muswell Hill-road, N.

PRESENTATION TO A MEDICAL MAN.—On the occasion of the presentation of the certificates to the successful students of the "Home Nursing Class" of the Ware Division of the St. John Ambulance Association, held at the Mission Hall, Amwell End, on June 12th, Mr. A. J. Boyd, M.D. Dub., was the recipient of a pair of silver candlesticks and a silver penholder as tokens of gratitude for his able instructions to the class.

ON CHYLOUS ASCITES, WITH AN ILLUSTRATIVE CASE.[1]

BY J. HALLIDAY CROOM, M.D., F.R.C.S., F.R.S. EDIN.,
GYNÆCOLOGIST AND LECTURER ON DISEASES OF WOMEN TO THE ROYAL INFIRMARY, EDINBURGH; CONSULTING PHYSICIAN TO THE ROYAL MATERNITY HOSPITAL, EDINBURGH.

OBSTRUCTION of the thoracic duct, especially if it be gradual, may give rise to no symptoms whatever during life, since anastomotic channels are established through which the lymph and chyle enter the circulation. In other cases, however, congestion of the lymphatic system gives rise to definite signs which can be clinically recognised, and this is especially so when the lacteals of the abdominal cavity are within the area affected. A few cases have been recorded in which chylous fluid was found in the pleural cavity, but in all these this was only secondary to a similar effusion into the peritoneal cavity. Only some 63 cases of chylous ascites are recorded, so that it is an extremely rare condition, and I therefore feel justified in bringing the notes of the following case before the society.

A woman, aged 39 years, was sent to the Royal Infirmary, Edinburgh, by Dr. J. T. Prangnell of Falkirk, on Sept. 29th, 1899. She complained of swelling of the abdomen and gradually advancing weakness and emaciation. Up to within three months of admission she had enjoyed good health. She had had six children—the youngest being three and a half years old—and menstruation had been normal and regular. For two months she had noticed the gradual enlargement of the abdomen and had been losing weight. The patient was found to be generally somewhat emaciated and the examination of the abdomen revealed considerable distension evidently due to ascites. The superficial veins were much distended, the skin was somewhat deeply pigmented, and on deep palpation several irregular hard masses could be detected in the umbilical and epigastric regions. A diagnosis of cancer of the omentum and mesentery with resulting ascites was arrived at. For some time, with careful dieting, the patient's general condition distinctly improved, but occasionally for a day or two she had a relapse showing itself in nausea and vomiting. After being three weeks in hospital she was, however, on the whole, distinctly better, although the distension of the abdomen was greater and caused her much more inconvenience.

On Nov. 2nd the abdominal cavity was aspirated and 380 ounces of fluid were removed. This fluid presented a remarkable appearance. At first sight it was exactly like pus, but when placed in a specimen glass it seemed much more mobile. The fluid had a pale yellow colour with a suggestion of opalescence, and at first it was quite homogeneous, showing no deposit, but after standing for about 24 hours a slight creamy layer was found on the surface. It had a sweetish milky odour. Dr. T. H. Milroy kindly examined the fluid for me and reported as follows:—"The fluid which was sent to me consisted partly of finely emulsified fat, but more largely of a granular débris consisting mainly of fat. About 2 per cent. of fat was present. The pigment present was lutein." The granular débris was found on microscopical examination to consist of leucocytes in a state of fatty degeneration. After withdrawal of this fluid examination of the abdomen revealed a moveable tumour in the region of the gall-bladder and an indefinite irregular solid mass was detected in the region of the greater curvature of the stomach. The aspiration of the abdomen relieved the patient of her symptoms for some time, but she still suffered from occasional vomiting and inability to take solid food. The vomited matter was examined frequently, but contained no blood. From Nov. 16th—that is, about a fortnight after the tapping—remarkable and specially pronounced emaciation set in, while the abdominal cavity became more and more distended with fluid. The discomfort induced by rapid accumulation was so great that, although the patient was evidently sinking rapidly, she was tapped again and about 350 ounces of fluid were removed. The fluid presented exactly the same characters as before. The patient, however, did not seem to improve in the least, but gradually got worse and died five days later, on Nov. 26th.

[1] A paper read before the Obstetrical Society of Edinburgh on March 14th, 1900.

A post-mortem examination was made by Dr. D. A. Welsh of which the report was as follows:—"The body showed marked emaciation and the skin was jaundiced. Thorax.—Pericardium and heart were practically healthy, but the heart was small and showed some brown atrophy. Each pleural sac contained about six ounces of bile-stained fluid. The subpleural lymphatics were studded with minute cancerous nodules; these were not found in the substance of the lung. There were signs of chronic bronchitis and emphysema. Abdomen.—A few ounces of turbid bile-stained fluid were removed from the abdominal cavity. The small intestine showed some commencing peritonitis. The mesenteric glands were generally enlarged from malignant infiltration. The stomach was much shrunken and filled with deeply bile-stained mucus. A large cancerous neoplasm was growing from the inner surface of the anterior wall, extending from an inch from the pylorus for four inches along the lesser curvature. In appearance the tumour was a soft fungating mass raised about one inch above the surface of the healthy mucous membrane and presented some ulceration in the centre. The tumour consisted largely of soft gelatinous tissue, but was evidently malignant in nature and had undergone extensive colloid degeneration. The gall-bladder was distended with bile and the glands and tissues along the larger bile-ducts and in the porta of the liver were extensively infiltrated with cancer. The liver itself contained one small cancer nodule. The spleen was healthy, but the kidneys were somewhat cirrhotic and fatty. The small intestine was throughout its whole length greatly thickened and contracted. It showed an immense number of small cancer nodules surrounding the lacteals close to the mesenteric attachment. The lacteals were very extensively occluded. The thoracic duct and the receptaculum chyli were carefully dissected out and were found healthy. There was, however, a mass of infiltrated glands lying close beside and pressing on the receptaculum."

Remarks.—The cause of chylous extravasation is either an obstruction to the flow of chyle or a distinct rupture of the thoracic duct or of the receptaculum chyli. A few cases of rupture have been recorded—as, for example, by Quincke—in which chylous hydrothorax resulted, and Wilhelm reports a case in which the accident occurred during an attack of whooping-cough. Whitla has also recorded a case of rupture. Rokitansky records a case of peritoneal and pleural effusion in which the fluid was chylous in nature. It was associated with mitral regurgitation and cardiac dilatation. In my case the chylous effusion seemed to be due to an obstruction to the flow of chyle at the junction of the intestinal mesenteric lacteals. The thoracic duct itself was normal and the pressure of the cancerous glands around the receptaculum was probably not sufficient to occlude it. Thus in some cases the lesion was in the thoracic duct itself, whereas in others it has been due to congestion of the larger lymphatic capillaries or of the smaller lacteals within the mesentery itself. In most of the cases the termination has been fatal, due partly to the original disease and partly to the consequent starvation. Some authorities have endeavoured to differentiate between a true chylous ascites and an ascites adiposus or chyliformis. Microscopically the fluids are similar in appearance, but on chemical and microscopic examination the differences are detected. Senator adopts Quincke's classification and distinguishes the two as follows. In chylous ascites the microscope reveals very finely granular fat cells and an absence of large fat-globules; and in adipose ascites chemical examination shows the presence of sugar; it shows similar but much larger fat cells, lymph cells, and in some cases cancer cells. This variety occurs chiefly in tuberculous or malignant peritonitis and is a result of a fatty degeneration of the serous endothelium and of lymph and pus cells. Although this view is very generally accepted a few authorities maintain that the difference cannot be held to be absolute, for they assert that since sugar is absorbed chiefly into the portal circulation direct, and only a minute quantity, if any, by the lacteals, the presence or absence of sugar cannot be considered of any importance in differentiating between the two conditions. Further, they seem disinclined to believe that fatty degeneration of endothelial tuberculous or cancerous cells could occur to such an extent as to give ascitic fluid such definite characteristics.

In a recent paper read at the Société Médicale des Hôpitaux M. Fernand Widal and M. Prosper Merklen discussed lactescent ascites of lymphatic origin. They pointed out that many authorities regarded milky fluid in the abdominal cavity as chylous in nature. Others, however, consider that the fat might be due to fatty degeneration of extravasated cells. M. Lion first showed that milky ascitic fluid might be other than chyle. In a case of cancer of the ovary he found that the liquid contained a substance analogous to casein, but no fat. M. Aschard and M. Apert respectively published cases in which the fluid when examined under the microscope showed no fatty globules but innumerable minute refractile granules. M. Widal and M. Merklen hold that the distinction between chylous and non-chylous ascites presents great difficulties and, further, that in the chylous variety the quantity varies very much in different cases and even at different times in the same case. They also point out that the kind of leucocytes found in the effusion show that chylous ascites may be lymphatic in origin and they record an illustrative case. Microscopic examination of the fluid removed showed no fatty particles but abundance of leucocytes, 90,000 to 100,000 per cubic millimetre. Only cells of different sizes, all with a single nucleus, were discovered. At the necropsy no peritonitis was found and even though there was no apparent lesion of the abdominal lymphatics the milky liquid was proved to be lymphatic in origin. The patient had cirrhosis of the liver and tubercle of the lungs.

Edinburgh.

A PLEA FOR EARLY OPERATION IN CASES OF UNDOUBTED TUBERCLE OF THE LUNG.

BY J. FOSTER PALMER, M.R.C.S. ENG., L.R.C.P. LOND.,
PRESIDENT OF THE CHELSEA CLINICAL SOCIETY.

IN bringing forward the following suggestions with respect to the excision of portions of lung tissue in cases of tubercle I am met by two special difficulties. The first is that which must inevitably arise of persuading any patient, feeling comparatively well and suffering only from a small patch of tubercle, to submit to a more or less formidable operation for its removal. The second arises from the same cause and consists in the absence of actual cases of operation of the special kind referred to. I must therefore base my observations, chiefly on anatomical considerations, on accidents affecting the lung tissue and on those somewhat rare cases in which operation on the lung has been found necessary for other and graver reasons. The difficulties will no doubt disappear as the public mind becomes more familiar with surgery, but this can only take place concurrently with its progress in the direction here indicated.

The prognosis of tuberculosis is always difficult, its medical treatment vague, empirical, and uncertain. It is only surgery which offers a really good prospect of success. Some may be disposed to question this, but the fact is in practice admitted, for when any other organ than the lung is attacked extirpation is the first remedy proposed and it is usually attended with success. Tubercle in the joints, tubercle in the glands, lymphatic or otherwise, in the bones and muscles, in the skin, in the abdomen and pelvis is successfully treated by operation, while the lungs—in which, after all, the greatest havoc is wrought by this disease—remain practically unexplored by the surgeon's knife. The futility of all other treatment was recognised a hundred years ago by John Hunter. "Internal remedies," he said, speaking of scrofula, "have very little power."[1] "Local applications—especially those of a stimulating kind—all prove injurious."[2] "As to external parts, the only certain cure is extirpation."[3] "The best surgical treatment for those cases which will not admit of removal is to do nothing."[4] He finally emphasises his opinion by the statement that short of complete extirpation even "cutting always does harm."[5] In principle all these statements still hold good. In practice they mean something very different. Then they meant that most cases were incurable. Now they mean that most cases are curable. The area of surgery has enormously increased since Hunter's time. Indeed, it has been revolutionised. Then the cases that would admit of removal were few. Now the

[1] Works of John Hunter. Palmer's edition, vol. i., chapter xxi., p. 598.

exceptions are few and surgical treatment is the rule. The principal exception, however, is just that region of the body where the greatest havoc is wrought by the disease. If "the only certain cure is extirpation"[6] extirpation ought to be universal, and our chief object should be to bring these great and highly susceptible organs within the scope of surgery. This does not mean the extinction of the physician. It means a development to the highest pitch of his accuracy of diagnosis, as well as of the observation of the bacteriologist and the skiagraphist, and of the thought, skill, and judgment of the surgeon. It is true now, as it was in Hunter's time, that "parts frequently get well of themselves." But it is equally true that still in some cases "the only certain cure is extirpation."[7] To decide which these cases are will tax all our powers of observation and diagnosis.[8]

The danger, generally speaking, of wounds of the lung is well known and has been recognised from the earliest times. πάγη δ' ἐν πνεύμονι χαλκός.[9] In this case death does not seem to have taken place until the abdomen was also ripped open with a sword. 3000 years ago it was understood that wounds of the lung were not immediately fatal.[10] The experiments of Professor A. Richet of Paris[11] on the living dog showed that the total collapse of one lung from opening the pleura caused a considerable degree of dyspnœa (suffocation he called it), but very rarely an immediate fatal result. In man, he says, the case is different: the sudden loss of so large a proportion of the breathing apparatus causes fatal suffocation.[12] He gives one case (from the "Bulletin de Thérapeutique," 1842, tome xxii., p. 358) in which death occurred several hours afterwards from an accident in which the pulmonary pleura was torn open and the lung collapsed; and another (from the "Archives de Médecine," 1840, tome ix., p. 489) in which death took place in three hours, when the right lung was found torn in three places and so collapsed as to be hardly visible. In this case the injured lung was normally the larger of the two.[13] On the other hand, Professor Longmore, in Holmes's "System of Surgery," in his article on Gunshot Wounds, states that "when the compression is limited to one lung, though it may be completely collapsed in consequence, especially if the opening in the chest wall be a large one, the symptom of dyspnœa may be wholly absent."[14] This, however, must be unusual. Indeed, all observers, both ancient and modern, are agreed that traumatic pneumothorax is a condition of great danger, though far less fatal than that resulting from ulceration of the pulmonary pleura from disease.[15] The traumatic form, too, when it affects only one side appears to be rarely fatal immediately. The danger is, *ceteris paribus*, in proportion to the degree of collapse.

This, then, is the most important danger in connexion with all operations involving the lung and pleura. The cause of this danger is an active and not a passive one. It was formerly taught that collapse of the lung in wounds of the chest-wall was due to atmospheric pressure. It is sufficiently obvious, however, that when the pulmonary pleura is intact and the parietal pleura opened the pulmonary pleura is subject to atmospheric pressure on both sides—on the outside through the hole in the chest-wall and on the inside through the trachea. These two are equal and contrary and as they must thus neutralise one another cannot either of them be adequate to cause collapse. There is evidently an active vital force at work also, and this is the retractility which is inherent in the elastic tissue of the lung and is one of the factors in ordinary expiration. The experiments of Richet on the dead subject proved this to demonstration. When the lung was healthy and free from adhesions collapse invariably took place on performing artificial respiration after making a subcutaneous incision into the lung by means of a tenotomy knife.[16] When congestion, or even emphysema, was present in the lung the retractility, of course, was incomplete.[17] But the principal condition which intervenes to prevent collapse of the lung is adhesion of the pleural surfaces. The prevalence of this condition accounts no doubt for many of those cases of gunshot and other wounds of the lung which would otherwise be fatal.[18] In operations on the lung the same holds good. After all, what is the normal condition of the pleura, adherent or non-adherent? Adhesion is due to a morbid process and must therefore be pathological. But a process which after a certain age appears to have taken place in the majority of a species, and which tends to save life after operation or accident, if pathological, can hardly be considered abnormal or unnatural. A condition so prevalent, although apparently subject to no special rule, is anomalous on account of its extensive incidence and its protective influence in certain injuries. It is difficult to see why, important as pleuritic adhesions are in preventing collapse of the lung, all people should, as we suppose, be born without them and that a large proportion should subsequently develop them as a pathological condition. The statistics of their actual incidence it would be interesting to know. A good working majority might sometimes tend to justify an operation.

"Perhaps there is hardly one in fifty," said John Hunter, "who at the age of fifty is without adhesion of the lungs to the pleura."[19] If this is correct—and Hunter was a great dissector and an accurate observer—it looks well for operations on those over fifty years of age, but this is not the age at which we usually expect to meet with incipient tubercle, although it is by no means uncommon even at a much later age. In 1845 Richet, in making some researches on the lymphatics of the lungs, dissected 75 subjects. Of these 150 lungs 36 only were free from adhesions.[20] In this instance he was selecting healthy lungs as far as possible. Ordinarily the proportion of adherent pleuræ was much greater. "Pour mon compte," he says, "depuis plusieurs années que mon attention est attirée sur cette disposition, c'est à peine si j'ai rencontré un sujet sur deux dont les poumons fussent complètement libres dans la cavité pleurale."[21] These figures, however, as far as I have been able on a small scale to test them, seem to be hardly borne out by the experience of some of the more recent examinations. Of 283 cases recorded in the post-mortem book at St. George's Hospital for 1892, 149, or 52 per cent., appear to be free from adhesions or other affections of the pleura; 100, or 35 per cent., to present old adhesions; and 40, or 14 per cent., effusion or growths in the pleura. Of the 149 subjects with healthy pluræ 34, or 22·7 per cent., were over 50; of the 100 with old adhesions 34, or 34 per cent., were over 50; and of the 40 with present pleural mischief eight, or 20 per cent., were over 50. The average age of the cases free from adhesions was 38, of those with adhesions 39·8, and of those with recent effusion 34

[8] I am not referring now to the electric cautery, the "point de fer" treatment, as it is called. This is already on trial and has been employed, I believe, with some success, especially in Paris. I refer to genuine cutting operations with the knife, in cases where it may be necessary to remove bodily large or small portions of the lung, or in which the "point de fer" treatment is for any reason inadmissible or insufficient.

[9] Iliad, Δ 523.

[10] This fact has been emphasised more than it has ever been before by the large proportion of recoveries from wound of the lung among the troops now fighting in South Africa. The antiseptic treatment has given such wounds fair play and the opportunity of running their normal course, which in former wars they did not have. In them the deaths were evidently due, not to pneumothorax or emphysema or hæmorrhage, but to septic poisoning.

[17] Professor Osler ("Principles and Practice of Medicine," p. 608) appears to be of opinion, based on the experiments of West, that the cohesion between the two pleural surfaces is normally in excess of the elasticity of the lung and is thus in many cases sufficient to prevent collapse. He admits, however, that in some cases pneumothorax has even followed exploratory punctures with a hypodermic needle. It does not seem quite clear that in all these experiments, as in those recorded by Richet, the pleura was absolutely free from adhesions. If not it would explain the strange discrepancy between them and the cases last mentioned, in which adhesions were obviously absent.

[18] One of the first, if not the first, to point out this fact was Roux in a paper in the Bibliothèque Médicale for 1807, entitled, "Sur les avantages de l'adhérence du poumon aux parois de la poitrine dans les plaies pénétrantes de cette cavité." The large percentage of recoveries from wound of the lung already referred to among the troops in South Africa is probably due in some degree to the prevalance of this condition.

[21] Ibid.

The addition of phthisical cases, which are excluded from the hospital, but in which pleural adhesions are very largely prevalent, would perhaps raise the general incidence of this condition to more than 50 per cent.[22]

In operations of the lung where the pleura is free from adhesions pneumothorax, of course, is possible. Pneumothorax alone, however, and limited to one lung, is not by any means a necessarily fatal symptom. Phthisical cases (and these constitute nine-tenths of all cases in which the pulmonary pleura alone is perforated from disease) die from suppuration or spreading tuberculous mischief, but pneumothorax in an otherwise healthy person—and this includes traumatic cases—often ends in recovery.[23] Rarely indeed does death take place immediately. In the most severe cases recorded some hours have elapsed. It is evident, therefere, that in cases of operation, if a plan of treatment is decided on, there is ample time to carry it out and restore the parts to a more natural position long before fatal collapse ensues.

The first danger, then, to guard against in operations on the lung—and this is present only when the lung is practically free from adhesions—is pneumothorax. In wounds of the lung, however, it seems to be, from recent experience, a not very frequent condition. In his report of the battle of Tugela Mr. Treves gives, among numerous chest wounds resulting in surgical emphysema and hæmothorax, and a case or two of empyema, only one of pneumothorax.[24] In the report of the Spion Kop action he lumps together pneumothorax, hæmothorax, and empyema. Yet, "taken as a whole," he says, "this series of cases has done well."[25] Mr. Dent, in a report from Maritzburg on Feb. 10th, says that although "hæmothorax occurs pretty frequently" "pneumothorax" is rarely seen.[26] Sir William Thomson, writing from Cape Town on March 6th, says: "The penetrating bullet wounds of the thorax are numerous, but are all doing well."[27]

An experiment of John Hunter shows the natural tendency to heal of wounds in the lung and pleura. He shot a dog through the lung to see the process of suppuration in the pleura. "But," he says, "both nature and the dog cheated me, for ..... the dog would always lie on the wounded side. The lungs adhered to the wound and no further inflammation took place."[28] Notwithstanding the result in this case Hunter utters a strong warning against opening the pleural cavity even in cases of pneumothorax and surgical emphysema "because it will produce the suppurative inflammation all over the internal cavities and most probably make the wound in the lung ulcerate."[29] Meanwhile, surgery has made certain advances since the time of Hunter and suppuration is not now the universal bugbear which it was 100 years ago. The history of two recent cases of lung surgery will serve to show some of the possibilities in this direction. The first is a case related by Steiner of echinococcus of both lungs. The symptoms were those of disease of the liver and lungs with displaced heart and a loud murmur. On the left side the seventh and eighth ribs were resected at the back, the pleural cavity laid open, and the echinococcus removed. The lung immediately expanded and filled up the space formerly occupied by the echinococcus. In this case, which was that of a young girl, the operator, Professor Israel, did not trust to the existence of pleural adhesions but united the parietal to the pulmonary pleura by a circle of sutures round the tumour before operating. This is one certain method of avoiding collapse and pneumothorax. The patient recovered and the normal capacity of the lung was completely restored. The tumour on the left side came away through the bronchial tubes during an attack of broncho-pneumonia, but not without some permanent injury to the lung.[30] Surgical treatment, it seems, gave the best results. The second was a case of gangrene of the apex of the right lung operated on by Lejars at the Hôpital Beaujon. The patient was a man, aged 51 years, and, true to the dictum of John Hunter, the two layers of the pleura were adherent. Two inches of the second, third, and fourth ribs were resected in the subclavicular region. The lung was incised and a fœtid mass of filamentous tissue was extracted. The cavity was washed out with hot water, drainage-tubes were inserted, and the skin wound was closed and dressed with iodoform gauze. The operation was perfectly successful, but the patient died six weeks later from a second attack of gangrene, both lungs being infiltrated with tubercle. The opened cavity was healing.[31] It would seem that an early diagnosis of, and operation for, tubercle would have obviated all the mischief. An operation successful at this late stage and in such a condition of the lungs would, *a fortiori*, have been successful at an earlier period for the removal of tubercle at its first appearance.

Another method of preventing collapse and consequent pneumothorax is to excite adhesions artificially by irritating the layers of the pleura in the sound part of the lung beyond the seat of the mischief, thus blocking up that part of the cavity, leaving free, as far as possible, the tuberculous portion which it is intended to remove. This method, however, is objectionable on account of the well-known tendency of tubercle to spread in the lung after any form of pleuritic inflammation. A fourth method has been suggested by Matas in the paper already referred to.[32] His plan is to keep the lung inflated by continuing artificial respiration throughout the operation. This is done by means of a pair of bellows in connexion with an O'Dwyer's intubation tube passed into the trachea. This appears to be free from most of the objections which attend other methods and where there are no adhesions leaves the whole lung free both for exploration and for any operative proceedings that may be found necessary. By one or other of the above methods the danger of pneumothorax and collapse of the lung may be almost certainly avoided in pulmonary surgery. These methods are: (1) to sew the pulmonary to the costal pleura beyond the seat of the disease before operating; (2) to trust in certain cases to the existence of adhesions already formed if the physical signs give evidence of it; (3) to excite artificial adhesions in the pleura; and (4) to expand the lungs artificially from within. The last appears to offer the best prospect of success and can, moreover, be discontinued if extensive adhesions are found to be present.

The second danger is surgical emphysema. It is said that this condition may be fatal from its effect on the muscles of respiration or even from pressure on the phrenic nerve. Emphysema may result from four causes: (1) rupture of the trachea or larger bronchial tubes; (2) external wounds into the cellular tissues surrounding the costal pleura without lesion of the latter; (3) lesion of the costal pleura only with external wound; and (4) lesion of both pleuræ with or without external wound. The first two have no bearing on the subject. The last two are also causes of pneumothorax. Richet is of opinion that pneumothorax and emphysema do not usually occur together.[33] The air escaping from the lung into the cavity of the pleura would, it is argued, take the line of least resistance. This would be that of compressing the lung rather than of penetrating into the cellular tissue. When, however, the lung is fully collapsed there is no more alternate contraction and expansion and consequently no further escape of air into the pleural cavity. He considers that emphysema usually indicates *partial* adhesion. In this case the air escapes into the pleural cavity and, being unable to compress the lung on account of adhesion, penetrates into the cellular tissue. This, of course, would only occur when the external wound is small or non-existent. If it were large (as it would be in the case of an operation) the air would escape through it and emphysema would not occur. In a case under my care, however, occurring in a child in whom adhesions would presumably be absent, emphysema took place

[22] The attendant at the Chelsea mortuary, who has assisted at all the post-mortem examinations for 11 years, gives me nine in ten as the proportion of adherent pleuræ, but this is only a cursory and unscientific observation and there are no statistics.

[28] Works of John Hunter, Palmer's edition, vol. i., p. 444. Two striking cases of recovery from wounded lung are given in the "Annals of Surgery" for April, 1899. In one there was a perforating wound of the liver, kidney, diaphragm, and pleura by the shaft of a wagon. There appear to have been no (or only slight) adhesions, as a quart of blood mixed with bile and urine was removed from the pleural cavity. The other was a wound with a sharp instrument into the lung through the eighth intercostal space (Brit. Med. Jour., August 19th, 1899, Epitome of Current Literature, par. 135).

[32] Annals of Surgery, April, 1899. Brit. Med. Jour., May 13th, 1899 Epitome of Current Medical Literature, par. 343.

[33] This is, of course, in reference to cases where the air comes from the lung only.

over the chest, the neck, and the face.[34] The child, however, recovered rapidly and completely without any further symptom, and my opinion from cases I have seen, confirmed by the experience of the war in South Africa, is that emphysema is not necessarily, when uncomplicated, a particularly dangerous symptom. When the pulmonary pleura is intact the case is different. In Mr. Turner's case of rupture of the œsophagus at the Royal Medical and Chirurgical Society emphysema extended over the chest, neck, and face, and the lung was found to be totally collapsed.[35] It is doubtful, however, even in these cases whether the infiltration continues much after the collapse of the lung, as the suction of air through the external wound would then be much less powerful. In operations on the lung the conditions of emphysema should not occur. During the operation it is prevented by the free escape of air through the wound, while after the operation the entrance of air from without is prevented by its closure. From the experience of penetrating wounds at the seat of war the danger does not seem to be great. Sir William Thomson (March 6th) speaks of aspirating in some cases for hæmothorax but does not mention either emphysema or pneumothorax. Mr. Treves (Tugela) gives it (emphysema) as an occasional symptom, but the cases do well generally. At Spion Kop he gives pneumothorax, hæmothorax, and empyema, but no emphysema, while Mr. Dent (Feb. 10th), who refers to hæmothorax as common and pneumothorax as rare, makes no mention of emphysema at all.[36] In fact, surgical emphysema requires for its production a combination of conditions, some of which are usually absent, and although in operations on the lung it is possible for it to occur during the period which elapses between the closing of the external skin wound and the healing or blocking up of the wounds in the pleuræ, it is, for all practical purposes, a "quantité négligeable."

The third, and not the least important, danger is hæmorrhage. The pulmonary tissue is rich in blood-vessels, but these vessels increase in volume as we approach the pedicle and diminish towards the pleura. Therefore, as Richet observes, "superficial wounds, however large, are rarely followed by abundant hæmorrhage."[37] The earlier, then, that a tubercle is excised the less would be the danger. The history of gunshot wounds, too, shows that even when they are extensive the hæmorrhage is by no means necessarily fatal and that there is a considerable tendency to coagulation in the thick venous blood which issues from the arteries and capillaries of the lung. Among Sir W. Thomson's cases hæmothorax was not uncommon, but they all did well after paracentesis, and this seems to be the usual experience. In many other cases a single hæmoptysis was the only symptom, showing the natural tendency to a rapid cessation of hæmorrhage. In Israel's case the pulmonary pleura was possibly left intact, or wounded only to a very small extent. The question of hæmorrhage, therefore, did not arise. In Lejars's case the lung (or pulmonary pleura) was incised to a considerable extent, but here again hæmorrhage was presumably absent by reason of the morbid processes which had been going on in this part of the lung. Indeed, there is no mention of hæmorrhage. In cases where a cutting operation is required at the apex of the lung, and no adhesions are present, the diseased part, if not too extensive, might be included in a single ligature and the whole excised. In other superficial parts the same could be accomplished by drawing out the diseased part through the opening in the chest-wall with hooks or forceps. Where the disease is deeper or more extensive ligatures can be applied, after removal of the diseased portion of lung, to the larger vessels, the ligature in each case including the bronchial tube, with its accompanying artery and vein. In the first two classes of cases the most efficient method, perhaps, of preventing hæmorrhage would be by operating with the electric ecraseur. In the last the electric cautery could be applied after the use of the knife. In all the application of iodoform would be a useful adjunct, both as an antiseptic and a hæmostatic.

In all operations on the lung the introduction of bacteria from without, through the wound in the chest-wall, can be effectually prevented by modern antiseptic methods. But there is in these cases another channel of entrance for bacteria—viz., the trachea and bronchial tubes. The general experience of internal wounds of the lung where the skin is intact points to the pneumococcus as most to be feared in this direction. Pneumonia is the most frequent complication of rupture of the lung and the wounds caused by fractured ribs, injuries in which the trachea is the only passage for microbes, and which resemble in this respect operations on the lung with the external opening in the chest-wall hermetically sealed.

Royal-avenue, S.W.

[34] Reported in THE LANCET, Sept. 21st, 1878.

[35] Paper read before the society on May 27th, 1900. (Emphysema is very prevalent after this accident, probably on account of accompanying rupture of some of the larger bronchial tubes.)

ACROPARÆSTHESIA.

BY F. H. EDGEWORTH, B.A., M.B. CAMB., B.SC. LOND.,
ASSISTANT PHYSICIAN TO THE BRISTOL ROYAL INFIRMARY.

THE affection called "acroparæsthesia" has, as far as I know, not been described as occurring in this country, though it undoubtedly does occur, and always causes much distress and sometimes leads to inability to work. I shall preface a few general remarks on the subject by describing three cases.

CASE 1.—The patient, a married woman, aged 44 years, engaged in household work, came to the Bristol Royal Infirmary on Dec. 29th, 1898, complaining that on lying down at night her arms up to the elbows became "numb and dead" and "burned" so that she could not sleep. She had suffered in this way for four years, though more especially during the previous nine months. If she sat up in bed and rubbed her hands and arms the disagreeable feeling would get better, but it returned on lying down again, so that she could not sleep until she was quite worn out. She also suffered in the same way though in less degree during the daytime on using her hands. The hands did not change colour during the attacks, nor did she lose the power of feeling with them or of moving them. But for this she considered herself quite well and could not remember having had any serious disease. She menstruated regularly and did not suffer from flushes or anything else suggesting the onset of the change of life. No symptoms which might be hysterical had occurred. On examination no evidence of anything amiss was found; there was no weakness or wasting of the muscles of the arms; the elbow jerks were absent; sensation for touch, heat, cold, and pain was intact; the skin was of a natural colour; and the radial arteries and pulses were normal. The thoracic and abdominal organs and the urine were healthy. There were no hysterical stigmata. On asking her to repeatedly pick up a pin from the table she said, after a short time, that the numbness and burning feeling were coming on, but no vaso-motor change was apparent and sensation was still preserved.

CASE 2.—A widow, aged 48 years, a waistcoat maker, came to the Bristol Royal Infirmary on Dec. 14th, 1898. She said that for the previous three months she had suffered from a dead tingling feeling in both arms, at first in the left hand and afterwards in the right one also. When she was not doing anything she had the dead tingling sensation in the thumbs and fingers only, but on using the hands for any length of time this became much worse and gradually spread up to the elbows. She was consequently unable to earn her living and had to fall back upon parish relief. The feeling did not become worse at night and she could sleep well. The menopause had occurred nine months previously and she suffered much from flushes. As in the previously related case, nothing abnormal could be found on physical examination even when she had been using her hands for a considerable time.

CASE 3.—In this case the patient was a charwoman, aged 41 years. She came to the Bristol Royal Infirmary on Feb. 21st, 1900, and said that she was unable to do anything because using the hands brought on a dead tingling feeling in them which spread up to the elbows and was accompanied by a cramp-like pain, though there was no actual cramp of the muscles. This had been coming on for about five months and was gradually getting worse. She had had to give up her employment and she could not even dress herself or comb her own hair. When sitting quietly and not using her hands she had no tingling, dead feeling, or pain. At night the fingers felt as if they were swollen, though they did not actually swell, so that she took off her wedding-ring

on going to bed. The menopause had taken place four months previously and at times she went "all of a fever." On examination nothing abnormal could be found either when she was at rest or when she was using her hands and suffering from the tingling and dead feeling.

These cases are closely similar to those which have been already recorded by Schultze,[1] Chabot,[2] and Lereboullet.[3] The patients were women, between 40 and 50 years of age, engaged in earning their living by manual work, and otherwise in good health. The abnormal sensation complained of was a dead, tingling feeling in the hands and arms, which occurred either at night (as in the first case), or on using the hands (as in the first and third cases), or persistent though much worse on manual labour (as in the second case). In all three cases no objective sign of anything abnormal was discovered either when the patients were free from or suffering from the abnormal sensation. No symptom or sign of hysteria was present.

The pathology of acroparæsthesia is unknown. According to Lereboullet the fault lies in the peripheral venous circulation which, by producing ischæmia, or it may be passive hyperæmia, results in serous infiltration of the terminal branches of the nerves. And certainly in some instances objective signs of vaso-motor disturbance have been noted. But this theory would cover at most a few only of the recorded cases and does not, for instance, explain those described above in which no vaso-motor changes were apparent. The origin of the disease is probably to be found in the age and sex of the patients and the affection may be related to those other abnormal actions of the central nervous system which are so apt to occur in women during the years preceding and following the menopause. The diagnosis should be based on the conjunction of these abnormal sensations with an absence or insignificance of signs of vaso-motor disturbance.

The affections with which acroparæsthesia is most likely to be confounded are hysteria, peripheral neuritis, erythromelalgia, acrocyanosis, acromegaly, and arterial degeneration. Cases of hysteria simulating acroparæsthesia may be diagnosed by the history or by the associated physical signs. Two such cases are the following.

CASE 4.—A woman, aged 43 years, came to the Bristol Royal Infirmary on Jan. 2nd, 1898, saying that for some months she had had a constant "dead" feeling in both arms, which was so distressing that she could not sleep at night or do anything by day. No objective sign of anything wrong could be detected. On making further inquiries she said that she also suffered from a lump rising in the throat and threatening to choke her and that a month previously she had had a fit lasting, she was told, about an hour. The symptoms point to this case being one of hysteria.

CASE 5.—The patient, a man, aged 50 years, a tailor, came to the Bristol Royal Infirmary on July 10th, 1899, complaining that he had a dead, tingling feeling in the right arm and hand lasting all day and preventing sleep at night, also that he could not feel properly with his right hand; for instance, he did not know except by looking whether his thimble was on or off. This condition had lasted for over a year and it was somewhat variable, being worse when his "nerves were low." On examination it was found that a slight right hemianæsthesia existed which was more marked towards the extremity of the upper limb. There was general contraction of both fields of vision and absence of both plantar reflexes, whilst the tendon jerks, abdominal and cremasteric reflexes, and muscular system were normal. This was obviously a case of hysteria.

As a rule, peripheral neuritis can be easily distinguished from acroparæsthesia, though in some cases sensory disturbances may be paroxysmal and resemble those of the latter disease, as is shown by the following case.

CASE 6.—The patient, a tailor, aged 65 years, came to the Bristol Royal Infirmary on April 24th, 1899, saying that he had been ill for three weeks suffering from pain and a dead, numb, pricking feeling in the left hand and arm; this was not constant, but in attacks of from two to three hours' duration several times a day. During these attacks he could not feel to pick up a pin. On examination there was found to be a general weakness of the muscles of the left arm and a blunting of sensibility for touch and pain below the elbow, increasing in degree towards the ends of the fingers and not limited by the distribution of individual nerve trunks. The nerve trunks in the posterior triangle of the neck and in the bend of the elbow on the left side were tender on pressure. No other abnormal signs were present and no history of traumatism, rheumatism, or gout was elicited. A blister on the neck and salicylate of sodium soon relieved him, and on June 5th muscular power and cutaneous sensibility had returned, though the tops of the fingers were said to be still "dead and tingling" at times.

Erythromelalgia can be distinguished from acroparæsthesia by the associated marked vaso-motor changes, by its affecting the feet and legs almost exclusively, and by its dependence on the position of the limb.

Acrocyanosis may be accompanied by abnormal sensations resembling those of acroparæsthesia; the paroxysms, however, are not dependent on using the hands but, at least at first, on external cold, and are always accompanied by well-marked signs of vaso-motor change.

In acromegaly the abnormal sensations in the arms and hands may, as the following case proves, closely simulate those of acroparæsthesia.

CASE 7.—A woman, aged 34 years, came to the Bristol Royal Infirmary on Sept. 27th, 1899, complaining that both her hands and arms felt dead and tingling, especially on first awakening, so that she could not dress herself in the morning. The tingling gradually wore off as the day went on. She had had this for the previous two years and it was gradually getting worse. She had also noticed for about the same length of time that her hands and feet were gradually increasing in size, more especially in breadth. It was found on examination that she had the spade-like hands, broad feet, and coarse features of acromegaly. There was neither anæsthesia of the hands or arms nor evidence of vaso motor disturbances. Under the administration of thyroid and pituitary extracts the abnormal sensations disappeared, though temporarily relapsing when she ceased for a time to take the medicine. The physical signs of acromegaly persisted.

In some cases paræsthesia of the hands may be dependent on arterial degeneration. The condition, however, may be distinguished from acroparæsthesia proper by the greater age of the patients, by the constancy of the abnormal sensations, by the presence of more or less anæsthesia, and by the existence of thickening of the arterial coats. The following are two such cases.

CASE 8.—A needlewoman, aged 60 years, came to the Bristol Royal Infirmary on Dec. 23rd, 1896, complaining of a constant dead tingling feeling in both hands which she had had for the previous nine months and which was gradually getting worse. The hands felt cold and numb and she could not readily pick up a pin or perform any delicate movement with them. She had generally drunk as much beer as she could afford. On examination the hands felt cold and looked bluish and slightly swollen. There was distinct dulling of sensibility to touch and pain in the hands and in the lower part of the forearms, more marked in the right than in the left hand. Muscular power was normal. The radial and brachial arteries were tortuous with thickened coats and the radial pulses were very small. The aortic second sound was somewhat accentuated and the apex beat was displaced a little outwards and downwards. The urine was normal and there was no dropsy. This condition persisted for the eight months during which she attended the Infirmary.

CASE 9.—The patient, a tailor, aged 65 years, came to the Bristol Royal Infirmary on April 9th, 1900, saying that he had a constant sense of numbness and tingling in both hands which had been gradually coming on since the previous November. This numbness and tingling got much better on putting the hands in hot water and when he became warm in bed at night. He also said that he could not feel with the fingers as well as he had been used to and had had to give up his employment. On examination it was found that there was some dulling of sensibility for touch, heat, and pain in both hands below the wrists without any definitely marked upper limit. Muscular power was good. The colour of the hands was normal, though they felt a little cold. There was no swelling. The radial and brachial pulses were small and the coats of the arteries were irregularly thickened. The aortic second sound was slightly accentuated and the apex beat was in the fifth space in the nipple line.

The condition in these two cases is probably to be attributed to arterial degeneration with resulting insufficient blood-supply to the extremities; in neither was there evidence of arterial thrombosis which, as is well known, may be the proximate cause of even gangrene in atheroma.

These various affections which simulate acroparæsthesia can thus be distinguished by the presence of physical signs which are wanting in that disease.

Acroparæsthesia is exceedingly persistent and very rebellious to treatment. It may last for years and seriously incapacitate the sufferer from earning a living. Quinine and galvanism have been recommended by Chabot and ergot is highly praised by Sinkler.[4] As far as my experience goes bromides combined with a small dose of nitro-glycerine were of most service. Under this treatment the first two cases described above completely recovered in six months.

Clifton, Bristol.

THE COMPARATIVE GERMICIDAL ACTION OF SOME DISINFECTANTS.

BY ARTHUR H. BURGESS, M.B., M.SC. VICT., F.R.C.S. ENG.,

RESIDENT SURGICAL OFFICER, MANCHESTER ROYAL INFIRMARY.

THE following experimental investigation was undertaken in order to ascertain the relative germ-destroying power possessed by some of the so-called disinfectants in common use when tested under conditions as precisely similar as it is possible to obtain. For this purpose their individual action was tried upon the same species of germ, of the same degree of virulence, under the same general environment, and for the same length of time, by means of a method which, briefly stated, is as follows: a pure culture of a germ having first been obtained, silk threads are impregnated with this and are afterwards exposed to the action of the disinfectant to be tested in a solution of known strength for a certain definite length of time, at the expiration of which they are removed, well washed in sterilised water, and placed under conditions known to be suitable for the growth and development of the germ in question. Should growth occur it is evident that the disinfectant in this particular strength of solution has failed to destroy the vitality of the germ; in other words, that disinfection has not taken place, and *vice versâ*.

The specific germ selected for these experiments was the bacillus coli communis, a bacillus which occurs normally in the human intestinal tract, and in health appears to be innocuous, but which under abnormal conditions may become markedly pathogenic. This bacillus possesses some very distinct advantages for the purpose of this investigation: it is extremely easy to obtain it in large quantity owing to the profuse nature of its growth on potato; it has many characteristic reactions by which it can be readily distinguished from other bacilli and by applying these at different stages in the course of the experiments it is possible to establish the purity of the cultures throughout; while, since it has, for a non-sporing bacillus, a comparatively high power of resistance to germicides, any results obtained with it may be held to apply even more forcibly in the case of other non-sporing bacilli, at any rate of such as are pathogenic. The bacillus was isolated from the stools of a young girl suffering from enteric fever by the method of successive gelatin plates. A pure culture having been obtained and proved by means of the characteristic reactions to be the bacillus coli communis, a stock culture was made on the sloped surface of agar-peptone bouillon in tubes and from these subcultures on potato were taken as required. These were made on the surface of freshly prepared sterilised potato medium, and were incubated at 37° C. for 10 days, when a profuse dark-brown growth, very characteristic of this bacillus, was found to have formed. This was removed with a thick sterilised platinum wire (care being taken not to carry along with it any of the potato medium), and mixed in a sterilised glass capsule with a little sterilised peptone bouillon so as to form a thick emulsion, into which the silk threads were immersed. These threads were cut from the finest "Turner's plaited silk," each being exactly one inch long, and were sterilised in a Koch's apparatus for one and a half hours in Petri's dishes, in which they were afterwards dried and kept till required for use. After immersion in the emulsion for 10 minutes the threads were transferred with sterilised forceps to a Petri's capsule, in which they were partially dried in the dark at a temperature of 24° C. for three hours by placing them in the "cool" incubator. They were next transferred to the disinfectant solutions to be tested, and after remaining in these for the allotted time were lifted out with a sterilised platinum hook, washed well in sterilised distilled water in order to remove any trace of disinfectant adhering to them, and placed each in a separate tube of sterilised peptone bouillon. These tubes were incubated at 37° C. for 10 days, being examined each 12 hours for the first 48 hours, after that daily. If no growth occurs the bouillon is perfectly clear at the end of this time; if it does occur the bouillon begins to show signs of turbidity at a period varying from 12 hours or even less to 72 hours. The presence or absence of growth is further shown by microscopical examination, and by the inoculation of gelatin plates. If no growth had taken place at the end of 10 days it was concluded that all the bacilli present on the thread had been killed by the disinfectant solution. In every case a control experiment was made precisely as above, except that sterilised distilled water replaced the disinfectant solution, and in each instance growth was found to be present at the end of 12 hours.

Objection may possibly be raised to the above method on the ground that some of the disinfectant solution might be carried over on the thread into the bouillon, and so, by its antiseptic or inhibitory action, prevent the development of bacilli in the thread which were not actually killed by it. To guard against this the threads were, as already stated, well washed in sterilised distilled water after removal from the action of the disinfectant, and as a further precaution all those tubes which exhibited no growth at the end of 10 days were re-inoculated from an emulsion of bacilli prepared as above and again placed in the incubator. In every such case growth occurred at the end of 12 hours, thus proving that the bouillon in these tubes was still a suitable medium for the development of the organism, and that their previous sterility was due, not to any transferred disinfectant, but to the fact that all the bacilli on the thread had been completely destroyed.

In order to establish a fair comparison between the germicidal effects of the various disinfectants tested I decided to allow the threads to remain in solutions of them for certain definite lengths of time, and to ascertain the weakest strength of any given disinfectant which would destroy all the bacilli on the threads in these times respectively—viz., one minute, five minutes, 10 minutes, 30 minutes, and one hour. For each strength of a disinfectant solution acting for a given time (e.g., carbolic acid, 1 in 20 acting for five minutes) six threads were used, each being subsequently placed in a separate tube of bouillon and incubated. In by far the majority of cases the result was the same in each of the six tubes, either positive or negative, showing that every care had been taken to prevent contamination of the threads in the process of transference from the disinfectant solution to the bouillon tubes. But occasionally, when approaching the limit of the germicidal power of the particular strength of disinfectant used, there was some discrepancy—e.g., five tubes might give a positive and one a negative reaction, or *vice versâ*, in which case the verdict of the majority was taken to be the correct one. If, however, the discrepancy were more than this—e.g., four and two, or three and three—the experiment was repeated with a second set of six threads, and the majority taken.

The following substances were tested: biniodide of mercury, perchloride of mercury, chlorinated lime, formal aldehyde, lysol, carbolic acid, izal, medical izal, creolin, Jeyes' sanitary fluid, Walker's I.X.L. disinfectant fluid, Condy's fluid, "sanitas" fluid, and boric acid. These experiments involved the inoculation and culture of some 2000 tubes of bouillon and were conducted in the laboratory of the Manchester Union Hospital, Crumpsall, during six months of my tenure of the resident medical officership there. The ultimate results obtained are arranged for ready comparison in the accompanying table, where, in addition to stating the weakest strength of each disinfectant necessary to kill the bacillus coli communis in the allotted times, I have in each case further stated that strength which just failed to do so.

In interpreting these results I wish it to be clearly understood that they are merely relative and can only be held to be absolute under the exact conditions laid down for these

[4] Philadelphia Medical News, 1894.

TABLE SHOWING RESULTS OF EXPERIMENTS.

Disinfectant.	Weakest strength of solution necessary to destroy the bacillus coli communis in the following times—

experiments—i.e., where the bacilli are freely exposed to the action of the disinfectant in solution, no albuminous matter being present. In the actual practice of disinfection such conditions are never met with, the most important difference being the presence of albuminous material in greater or less quantity. Especially does this apply to the case of perchloride of mercury, which forms a definite combination with albumin, resulting in the formation of a comparatively inert albuminate of mercury, and thus, to maintain its efficiency, the strength of the solution would require to be increased in proportion to the amount of albuminous matter present.

Biniodide of mercury.—This was brought into solution by the addition of iodide of potassium in quantity just sufficient to dissolve it, a stock solution of 1 part of biniodide in 500 of distilled water being first prepared, from which the more dilute solutions were afterwards obtained by the addition of the requisite proportion of ordinary tap-water. It will be noted that the germicidal power of this drug is far superior to that of any other used in these experiments, and as it does not precipitate with albumin the results obtained should hold good even in the presence of albuminous material, thereby contrasting with the perchloride of mercury.

Chlorinated lime (commonly called "chloride of lime").—This is a white powder which is only partially soluble in water, and after standing for a little the insoluble portion falls to the bottom. This was kept in suspension in these experiments by frequent shaking of the glass vessel containing the threads immersed in the solution, but I also found that the germicidal power was not in any way altered by previously filtering the solution so as to remove this insoluble portion. In the stronger solutions of this substance not only are the bacilli on the threads all killed but the threads themselves are destroyed and in a short time almost all trace of them disappears.

Formal aldehyde.—The solutions of this substance were prepared from Schering's formalin, which is a 40 per cent. solution of formal aldehyde in water, the latter itself only existing in the gaseous state. It must be clearly understood that the proportions stated in the accompanying table refer to formal aldehyde and not to formalin.

Izal and medical izal.—These two coal products are prepared by Messrs. Newton, Chambers, and Co., the latter being a refined preparation of the former specially adapted to medical and surgical use. I found no difference between them as regards their germicidal properties. It should be stated that the proportions given in the accompanying table refer to the product as sold for use and not to the proportions of izal oil, of which "izal" disinfectant is an emulsion containing 40 per cent.

Boric acid.—This substance has no claim to be regarded as a disinfectant, since its saturated solution failed to destroy the bacillus coli communis in any of the allotted times.

Manchester.

ACUTE GLOSSITIS COMPLICATING A CASE OF TYPHOID FEVER.

BY H. CAMPBELL THOMSON, M.D., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN AND PATHOLOGIST TO THE MIDDLESEX HOSPITAL; PHYSICIAN TO OUT-PATIENTS AT THE HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S-PARK.

THE patient, a woman aged 34 years, suffering from typhoid fever, was admitted into the Middlesex Hospital on Nov. 17th, 1899, under the care of Dr. J. Kingston Fowler, to whom I am indebted for permission to make use of the clinical notes of the case. The early symptoms of the attack consisted of weakness, languor, pain in the back, and shivering. The bowels were confined at first and later they became more freely opened, but diarrhœa was never a troublesome factor. There was no vomiting. The blood showed Widal's reaction and the urine gave Ehrlich's test. There was a well-marked rash on the abdomen.

The patient was from the first very seriously ill and in spite of all treatment her condition became gradually worse till on Dec. 16th the pulse was scarcely perceptible and she was evidently *in extremis*. On the 17th, at 7 P.M., the tongue was first noticed to be swollen and examination showed the swelling to be confined to the left half of the organ. This condition must have arisen very rapidly as the tongue had previously been examined at midday and there was then no sign of any swelling. The swelling was firm and did not fluctuate, the mucous membrane over it was reddened, it was tender when touched, and gave rise to some difficulty in swallowing. At 10 P.M. on the same evening the swelling had increased and it now involved the right half of the tongue. The size of the swelling made it advisable to take some steps to try to reduce it, and accordingly after the part had been anæsthetised with cocaine a grooved needle was passed into the tumour, but only a little blood escaped. The patient's general condition, however, was so bad that it was not considered advisable to take any further measures and a few hours later death occurred. A post-mortem examination was made on the following day and extensive intestinal ulceration was found which had terminated in general peritonitis from a perforation at the lower end of the ileum. The tongue was swollen, especially the left half, and the mucous membrane over it was reddened; there were also one or two superficial

ulcerations on the dorsum of the tongue. On section the tissues were reddened and swollen, but there was no suppuration present.

The condition is of interest both on account of its rarity and its importance, for it may be a very formidable complication, and in this case had the patient not succumbed to the intestinal lesions vigorous measures would, no doubt, have had to be taken to reduce the swelling.

A case which occurred in Dr. Osler's clinic has been recorded by MacCrae,[1] in which glossitis was the first symptom of a relapse after 24 days of normal temperature. The tongue was red, inflamed, symmetrically enlarged, markedly tender, and somewhat indurated as far back as could be felt. Cultures taken from the left half gave a negative result, and after puncturing, the swelling of this half diminished, showing, as MacCrae thinks, the line of treatment which should be pursued. In this instance the patient made a good recovery. MacCrae states that this was the only case of glossitis which occurred in over 700 cases of typhoid fever treated in the Johns Hopkins Hospital. He quotes Nichols as having recorded a case of "septic infection in typhoid fever" in which two days before death swelling of the right half of the tongue was noted. This case ended fatally. At the necropsy the right half of the tongue was red and swollen and on section small abscesses and hæmorrhages were seen. Cultures yielded streptococci and the bacillus coli.

The cause of glossitis in the course of typhoid fever is an interesting question. The large majority of the cases probably arise from secondary local infections, and the presence of superficial ulcers of the tongue is suggestive of this mode of origin in the case I now record. Other cases, however, would seem to be part of a general infection—as, for instance, MacCrae's case in which the glossitis was the first symptom of a relapse after 24 days of normal temperature.

Queen Anne-street, W.

IMPERFORATE HYMEN AND RETAINED MENSTRUAL ACCUMULATION.

BY HUGH HOWIE BORLAND, M.B., C.M. GLASG., D.P.H. CANTAB.,
LATE HOUSE SURGEON, GLASGOW MATERNITY HOSPITAL.

I WAS called on Jan. 4th, 1900, to see a girl, aged 13 years and nine months, who was complaining of diarrhœa, rigors, and abdominal pain. The history was that on Dec. 30th, 1899, she began to suffer from diarrhœa and on the following day abdominal pain set in. This state of matters continued more or less until Jan. 4th, when diarrhœa, bearing-down pains, dysuria, and, finally, retention of urine supervened. The mother stated that the girl had always enjoyed good health. She had never menstruated, but as bearing upon her present illness it was noticed when a child that there was a "large blue vein" about the lower aspect of the genitals. Nothing, however, in the way of operation had been done for it. The girl was in a condition of extreme distress, crying out with agony and throwing herself about in bed when paroxysmal pains set in. She was a well-nourished and well-developed girl with womanly configuration, having large, plump, and well-formed breasts. The lower aspect of the abdomen showed a large, round, globular tumour which rose out of the pelvis, reached from the pubes to two inches above the umbilicus, and was so tense and resistant that it simulated the gravid uterus. Fluctuation could not be elicited. The vulva was greatly bulged downwards and the perineum was distended. On separating the thighs, but without everting the labia minora, the vaginal orifice was seen to be completely occluded by a bulging membrane across which some minute blood-vessels were traced. The colour of the membrane was that of a bluish plum; it measured two and a half inches and one and a half inches from before backward and had a convex projection one inch in extent. Fluctuation was here easily obtained. There was a considerable bulging of the lower aspect of the vulva and adjacent parts. There was no dilatation of the anus, although there had been severe diarrhœa. Rectal examination revealed that the lower lumen of the bowel had been extensively encroached upon by a large balloon-like mass, which was smooth and elastic. This tumour had not only pressed upon the bowel, but had pushed up the anterior aspect of the vulva to such an extent that the meatus urinarius was practically occluded, causing complete retention of urine.

On a catheter being passed 40 ounces of urine were drawn off, and to clear out the bowels thoroughly castor oil was ordered. The parts were also prepared for operation next morning. In the interval, however, previously to my arrival the dense membrane had become perforated in the median line. This aperture was only able to admit a small probe, yet a considerable amount of treacle-like substance had oozed out, and thus there had come about that slow aspiration which most authorities recommend in treating such cases. The vulva and perineum were again thoroughly cleansed by a solution of lysol (1 in 200). An incision with a sterilised knife was then made from before backward in the entire extent of the membrane in the median line. The index finger was introduced into the now open vaginal orifice in order to induce a free flow of the retained menses. The mucous membrane of the utero-vaginal canal was found to be perfectly smooth and devoid of rugæ. Suprapubic pressure was avoided during the evacuation of the fluid, and to prevent re-uniting of the cut surface of the membrane a sterilised perforated glass tube containing iodoform and boric powder was inserted into the aperture and retained *in situ*. Pads of wood wool were then placed over the vulva and perineum and fixed in position with a double T bandage. The patient was instructed to put gentle pressure on the glass tube to keep it in position when passing urine, and her mother, the nurse, was instructed to cleanse the parts most carefully thereafter with lysol solution on each occasion. For diet the patient had milk only, and two grains of quinine were given every three hours. The recumbent posture was enjoined unless while taking food when the semi-recumbent position was to be adopted.

On Jan. 6th I found that the patient had passed a good night; her temperature was 98° F. and her pulse was 89. I removed the glass which was half filled with the treacle-like material. Examination per rectum showed that the balloon-like mass had disappeared. Examination per vaginam failed to detect the os uteri. There were now, however, well-marked rugæ felt longitudinally in the previously smooth-lined utero-vaginal canal. The retained menses were apparently well drained. The glass tube was sterilised and again inserted and the same kind of dressings were applied. The subsequent history of the case was quite uneventful. There was no rise of temperature and the girl was allowed to get up on Jan. 12th, on which date there was no discharge of any kind in the tube or on the dressings. On the 15th examination per vaginam revealed rugæ almost of a scirrhus-like nature. The uterus was found to be normal and the os closed. It was directed that the glass tube should be inserted twice a week for some time. On Feb. 17th (six weeks after the operation had been performed) the girl menstruated normally, being poorly for four days.

It will be observed that the patient had reached puberty, although she was barely 14 years of age, and the accumulation must have been going on for many months to judge from the size of the abdominal swelling. It contained over three pints of altered blood which continued to run for several days as the uterus slowly contracted. The girl was quite unaware that there was anything abnormal and stated most clearly that there had been no monthly periodic occurrence of pelvic or bearing-down pains whatever.

Previously to the era of asepsis and antiseptics incision of an imperforate hymen was not infrequently followed by fatal results from septic absorption. Gradual withdrawal of the fluid enables the uterus to accommodate itself to its diminishing contents, but, as Lewers has pointed out, if it is rapidly emptied contractions are set up, some of the fluid with septic matter from the air may be forced along the Fallopian tubes into the peritoneum, and death from peritonitis may result.

Newmilns, Ayrshire.

ST. PANCRAS INFIRMARY.

A CASE OF THROMBOSIS OF THE SUPERIOR MESENTERIC VEINS.

(Under the care of Dr. W. M. DUNLOP, medical superintendent.)

AMONG the many conditions simulating true intestinal obstruction there is none more interesting than thrombosis of the mesenteric vessels. Either the arteries or the veins may be affected; in thrombosis of the arteries the symptoms are very acute, but when the veins only are involved the more chronic forms of obstruction are simulated. Barth,[1] Bradford,[2] and Koster[3] have published cases of thrombosis of the mesenteric veins and 14 cases have been collected by Elliot. In most cases a diagnosis of intestinal obstruction is made and a laparotomy is performed. In one case in which the arteries were thrombosed the portion of bowel concerned was excised with success. For the notes of the case we are indebted to Miss Mabel Stevenson, M.B. Lond., junior assistant medical officer.

A man, aged 51 years, was admitted into the St. Pancras Infirmary in a state of extreme collapse. The patient could give very little account of himself, but stated that for some time he had been suffering privations and had had vague abdominal pain. Two days before admission he was suddenly seized with acute pain in the hypogastrium accompanied by vomiting. In this condition he was found by the police and taken to the infirmary. On admission he was evidently moribund, with subnormal temperature and pale and shrunken features. He complained of intense thirst, but the ingestion of the smallest quantity of food provoked copious vomiting of greenish-black fluid which was entirely free from fæcal odour. There was acute pain in the abdomen which was paroxysmal in character. The abdominal walls were flaccid, there was no abdominal distension or tenderness, and the respiratory movements were normal. A few hours later a quantity of bright red fluid blood was passed per rectum. The pain lessened considerably after this, but the patient quickly sank from exhaustion, death taking place within seven hours of admission.

Necropsy.—On post-mortem examination the body was found to be spare and thin, but not emaciated. The abdominal viscera were normal in position. Two feet of the middle part of the ileum were intensely congested, almost black in colour, but not distended. There was a sharp line of demarcation between the diseased and the healthy portions of the bowel, extending into the mesentery along the line of vessels supplying the affected part. There were no signs of peritonitis. On section the intestinal wall was thick and œdematous; the mucous surface was intact. The intestine contained some bloody fluid, similar to that passed before death, but no fæcal matter. The veins in the congested portion of the mesentery were uniformly plugged with firm, dark clotted blood; the corresponding arteries were pervious and healthy. The venous thrombosis did not extend beyond the affected part of the mesentery and no evidence of thrombosis was found in the rest of the venous system, neither could any cause for thrombosis be detected. The rest of the viscera were pale and shrunken, but showed no evidence of disease. The case was apparently one of primary thrombosis of the superior mesenteric veins.

MONSALL FEVER HOSPITAL, MANCHESTER.

TWO CASES OF PERFORATION OF THE INTESTINE DURING AN ATTACK OF TYPHOID FEVER TREATED BY LAPAROTOMY; ONE RECOVERY.

(Under the care of Dr. R. W. MARSDEN, medical superintendent.)

THERE is no more dangerous complication in typhoid fever than perforation of an ulcer. It is difficult to state with accuracy the mortality from these cases when treated medically, for in most of those in which the patients have recovered after apparent perforation a great doubt must always remain that perforation has not taken place, but we shall not be over-estimating the death-rate in such cases, when not treated surgically, if we put it as at least 90 per cent. Monod and Vauverts[1] have shown conclusively that the mortality in cases treated surgically is certainly less than this. Finney[2] collected 52 cases in which laparotomy was performed, and of these 17 patients recovered. In 1898 there had been recorded 83 cases and 16 recoveries, a mortality of a little over 80 per cent. This is still a high death-rate, but when we consider the low general condition of the patients we are justified in thinking the result good.

CASE 1.—On Nov. 23rd, 1899, a youth, aged 16 years, was admitted into the Monsall Fever Hospital suffering from typhoid fever. He had been ailing for a fortnight and on Nov. 22nd an examination of the blood had shown that it gave the Widal reaction. Clinically the symptoms were distinctive of a moderately severe attack of typhoid fever—i.e., rose spots, enlarged spleen, general bronchitis, a temperature of 104° F., &c.—but the abdomen was soft and free from tumidity, and there was only slight diarrhœa. On Dec. 10th he began to convalesce and the temperature remained normal until the 25th, when a relapse occurred. The relapse was only of moderate severity and was not accompanied by abdominal fulness or diarrhœa, and after 10 days—i.e., on Jan. 4th, 1900—it seemed to be terminating. The general condition of the patient at this time was extremely satisfactory. At 4.30 P.M. on that day, however, he complained of acute cutting pain in the abdomen, which caused the legs to be drawn up and was accompanied by an ineffectual desire to micturate. At 5.30 P.M. the pain was worse, the abdominal muscles were in a state of tonic contraction, and on percussion there was an absence of liver dulness at the ends of the eighth, ninth, and tenth ribs on the right side. The pulse was 88, the temperature was 99·2°, and there was no evidence of "primary shock." At 10.30 P.M. the condition of the abdomen was as described, there being a little fulness, but marked tenderness midway between the umbilicus and the right anterior superior iliac spine. In the interval a greenish fluid had been vomited on three occasions. As the patient was now looking much worse, the eyes being sunken, the pulse 120 and small, the temperature 102·8°, and the respiration of a purely thoracic type, Dr. Marsden decided to perform laparotomy.

The operation was done at 1 A.M. on Jan. 5th, 1900, apparently eight and a half hours after the onset of peritonitis. On opening the peritoneum through a median incision three and a half inches long, a considerable quantity of yellow serous fluid exuded, having a milky appearance from the presence of minute particles of lymph. The intestines were not at all distended—in fact, their walls were quite flaccid and soft. The first loop withdrawn contained a Meckel's diverticulum about one inch in length, and with this excellent landmark there was very little difficulty in finding the perforation, which was situated six inches to the cæcal side of it. It was small, round, about three millimetres in diameter, and, as usual, there was the increased quantity of lymph on the bowel in its immediate neighbourhood. The patches of lymph had a very "curdy" appearance and were readily wiped off. The perforation had occurred in the centre of a greatly thickened patch and had apparently arisen from a progressive ulceration, as there were no signs of sloughing at the edges. There were no peritoneal adhesions—in fact, there was a remarkable absence even of "stickiness" between opposed peritoneal surfaces, and though two and

[1] Revue de Chirurgie, March, 1897.
[2] Annals of Surgery, March, 1897.

a half feet of bowel were examined only one other inflamed patch could be detected through the walls. The perforation was closed by folding inwards and uniting the peritoneum from each side of the patch by means of interrupted Lembert's sutures. A large drainage tube being passed towards the pelvis, the abdominal cavity was thoroughly irrigated with warm saline solution and the operation terminated after lasting 30 minutes. The patient's general condition did not seem to have suffered any deterioration, and with the exception of repeated attacks of vomiting during the next 38 hours the further course was one of uninterrupted progress. The tube, which had been shortened daily, was removed on Jan. 10th as there was no discharge and the wound was allowed to heal. The patient left the hospital apparently perfectly recovered on Feb. 13th.

CASE 2.—A youth, aged 18 years, was admitted into the Monsall Fever Hospital on Jan. 30th, 1900, suffering from a moderately severe attack of typhoid fever. He had been ill for two or three weeks previously and from the above date to Feb. 8th, when the first indications of perforation occurred, there were no signs of improvement. Rose spots were numerous, the temperature continued between 102° and 104° F., the pulse remained about 120 per minute, there was marked general bronchitis, and he was delirious. There was only slight diarrhœa, and the distension of the abdomen, which was considerable on admission, had appreciably diminished. On Feb. 8th, at 8.45 A.M., he complained of pain in the abdomen after defecation, and an examination revealed general tenderness over the hypogastrium, with absence of liver dulness internal to the nipple line. At the same time it was noticed that the respirations were shallow, 44 per minute, and purely thoracic. At 2 P.M. the tenderness was more extensive and the liver dulness was absent internal to the anterior axillary line. The temperature remained steadily between 102° and 103°, but the pulse, which was small and 158 per minute immediately after the onset of the pain, fell to 144 by 4 P.M., so that, the preliminary shock having evidently passed off, Dr. Marsden decided to attempt a laparotomy.

The operation was begun apparently about eight hours after the onset of peritonitis. A median incision was made and on opening the peritoneum a considerable amount of light yellow milky fluid exuded. The bowel was found to be only slightly distended, but much injected, and there were no signs of adhesions between opposed peritoneal surfaces. A considerable length of the ileum had to be eventrated before the perforation could be found, and its situation was again detected by the increased amount of lymph upon the intestine in its neighbourhood. It occupied the centre of a thickened, œdematous patch, and its edges were distinctly sloughy, whilst thin fluid yellow fæces were exuding from the opening. It was closed, as in the former case, by interrupted Lembert's sutures, but owing to the œdematous condition mentioned the peritoneum was very friable, and after three unsuccessful attempts to hold the surfaces together the sutures had to be entered into the outermost part of the thickened area. There was evidence of numerous other inflamed patches in the bowel but there were no signs of another perforation, so that a tube being inserted into the pelvis the peritoneal cavity was irrigated with warm saline solution, and the operation terminated after lasting 35 minutes. At the end of the operation the patient was evidently collapsed, the temperature in the axilla being 98·4°, the extremities cold, and the face and hands slightly cyanotic. He rallied, however, and on the next day (Feb. 9th) seemed to be progressing favourably, but on the 10th he was distinctly worse and he died on the same afternoon 48 hours after the operation.

Remarks by Dr. MARSDEN.—Laparotomy for perforation of the intestine in typhoid fever is still sufficiently in its infancy to call for a record of the various cases in which this treatment is pursued, and the patients who have recovered are sufficiently rare to demand a detailed account of the individual cases in order that reliable statistics may be obtained for future guidance. It is with this object in view that I have ventured to report the above cases. It is impossible to imagine two cases which could better illustrate Keen's[3] statement when he says: "Naturally the cases operated on after relapses or toward the end of the acute febrile attack will result better than those in which the perforation, occurring earlier, requires the patient not only to recover from the operation but to have strength enough to carry him through the fever which has not as yet subsided." In Case 1 the patient was at the end of a relapse and evidently about to convalesce, whereas in Case 2 I think that the fatal termination was undoubtedly almost solely due to the typhoid toxæmia. Moreover, from a consideration of these two cases alone one cannot help concluding that such factors as age, time of operation after perforation, and type of case—i.e., whether a tympanitic abdomen preventing leakage of intestinal contents or a doughy abdomen allowing free extravasation—are insignificant as regards a successful issue compared with the general condition of the patient at the time of the operation.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Occlusion of the Central Retinal Artery on Both Sides.—The Arithmetical Triangle in Ophthalmology.—Dermoid Tumour of the Conjunctiva.—Periarteritis of the Retinal Arteries.—Illustrations of Forest Scenery executed by an Artist after Cataract Extraction.—Ophthalmitis associated with Basal Meningitis.—Exhibition of Cases and Card Specimens.

AN ordinary meeting of this society was held on June 14th, Mr. ANDERSON CRITCHETT, President, being in the chair.

Mr. W. H. JESSOP described a case of Occlusion of Both Central Arteries of the Retina. The patient was a woman, aged 35 years, married nine years, who had no children living. She had had one miscarriage soon after marrying and eight months ago she was delivered of a child at the ninth month which only lived a few hours. On Oct. 24th, 1899, on awaking she found that she could not see with the right eye, although she was quite well at the time and had had no previous illness except an attack of influenza nine years and epistaxis two years back which continued for some weeks. On ophthalmoscopic examination the eye presented the symptoms of embolism of the central artery. There was doubtful perception of light. The left eye was normal. On Dec. 28th, 1899, she suddenly at 11.20 A.M. lost the sight of the left eye, and on examination all the signs of embolism of the central artery were present and there was no perception of light. Both optic discs were now atrophied, the retinal vessels were reduced to mere threads, and in places there was a white thickened condition of the sheath (periarteritis). The vision of the right eye had improved to $\frac{6}{36}$, but with the left there was perception of light only. The patient had been treated with mercury by inunction and internally. The interest of the case was in the arteries of each eye being affected and in the fact that the only symptom and sign pointing to embolus was the suddenness of each attack. No possible source of the emboli could be suggested. This rather pointed to a retinitis being the predisposing cause, and considering the great improvement of the vision under treatment it was probably of syphilitic origin. The changes seen in the vessels pointed to arterial degeneration.—Mr. E. T. COLLINS described the case which he had shown before the society in 1897. The patient also had epistaxis and amenorrhœa. He suggested the possibility of hæmorrhage into the optic nerve-sheath.—Dr. J. ABERCROMBIE asked if the patient had any uterine disease and suggested that spasm of an artery might last long enough to cause gangrene.—Mr. R. W. DOYNE thought that after embolism the peripheral parts of the retinal vessels were usually somewhat larger than the central portion, and this not being so in Mr. Jessop's case was suggestive of arterial disease as the chief cause of the condition.—Mr. JESSOP, in reply, said that he agreed with Mr. Doyne and also stated that there was no uterine disease.

Mr. C. WRAY read a paper entitled "The Arithmetical Triangle in Ophthalmology: How to Use It and What It Reveals." This method of investigation was a new one and Mr. Wray's plan of using it was as follows. Determine the maximum negative error of refraction and assume provisionally, in accordance with the general law of error, that the positive errors will be equal in amount and frequency. The paper assumed the negative error + 11—that is, 1 D. under E.—and this suggested the use of the twenty-third

line of the triangle, with the result E. = 15 per cent., M. 26 per cent., H. 59 per cent., and myopia over – 6 D. 0.66 per 1000, the minimum number found in any province of France being 1 per 1000 (French army statistics). If the twenty-fifth line were used under the assumption that the commonest refraction is E., then there would be E. 13.2 per cent., M. 43.4 per cent., and H. 48.4 per cent. This would raise the myopes with over – 6 D. far over 14.7, the very highest number that occurred per 1000, and prove E as the commonest refraction impossible. It would appear as though the highest myopia transmissible was – 11 and that the maximum grades were due to non-hereditary causes acting in addition. Mr. Wray deduced that there was no evidence that the effect of civilisation was as serious as it was usually thought, seeing that an increase of 1 D. in the commonest or normal refraction was an impossible and unnecessary hypothesis. Indeed, in that case there would be three cases per 1000 with over 6 D. of myopia from heredity alone, not counting those classed as over 6 D. from such patients generally preferring a – 6.5 lens, spasm of accommodation, &c. Seeing that the maximum is 14.7, very little room is left for the causes that operate seriously in producing acquired myopia.

Mr. SIMEON SNELL (Sheffield) related a case of Congenital Papilloma of the Conjunctiva which occurred in an infant, aged five months. The tumour hung from between the eyelids and fell over the lower lid at about its outer third, the lower part of the growth being enlarged into a rounded ball of about the size of a small pea. It was attached to the conjunctiva about halfway between the corneal margin and the inner canthus, and somewhat broadened out at this attachment. The stalk measured about half an inch, but traction readily lengthened it to an inch. The growth was snipped off with scissors. Mr. Treacher Collins had kindly examined the specimen and he had reported that its microscopical appearances were similar to those of a dermoid cyst of the eye.—Mr. J. GRIFFITH thought that the case should really be called a dermoid tumour, and with this opinion both Mr. COLLINS and Mr. SNELL agreed.

Mr. SIMEON SNELL related a case of Periarteritis of the Retinal Arteries and exhibited an Ophthalmoscopic Drawing. The patient was a woman, aged 43 years, and when first seen the sight in the right eye had been failing for about four months. On ophthalmoscopic examination a peculiar appearance of the arteries on the optic disc was observable. The arteries were encased in a snowy-white and somewhat glistening sheath. This appearance extended only a short distance beyond the optic papilla, and was confined chiefly to the arteries on the expanse of the disc. The vision equalled $\frac{1}{60}$. There was only one small hæmorrhage in the retina but now there were two others on the disc. In the left eye the appearances were very much less marked but the disease was evidently commencing. The vision equalled $\frac{6}{9}$. The urine contained a trace of albumin and there were granular casts. The arteries were rigid and tortuous and there was hypertrophy of the left ventricle. Reference was made to Mules's case recorded in the second volume of the Transactions of the Ophthalmological Society of the United Kingdom, but in the present instance, whilst the changes were confined to the optic disc and its immediate neighbourhood they appeared to be much more pronounced.—Mr. JESSOP asked if the fields of vision were contracted and, in reply, Mr. SNELL stated that such was the case.

Mr. SNELL also exhibited an Illustrated Book on Forest Scenery. The interest attaching to the work was that the illustrations, which were very numerous and of a high-class character, had all been executed by a gentleman, a patient of his, who had several years before undergone extraction of cataract in one eye. The other eye was useless for visual purposes owing to complete cataract. The same gentleman, an amateur artist, had been a successful exhibitor at the Royal Academy, but before the operation his paintings had not been accepted.

Mr. SYDNEY STEPHENSON read notes of a case of Ophthalmitis in a child of seven months associated with Simple Posterior Basic Meningitis. An effusion of lymph into the anterior chamber of one eye was soon followed by closure of the pupil, diminution of tension, and shrinking of the globe. Death took place on the thirty-third day of the disease which was characterised by retraction of the head, convulsions, progressive wasting, and fluctuating temperature. At the necropsy lympho-pus was found on the medulla and surrounding parts and could be traced along the crura, the optic tracts, and the commissure to the left optic nerve. The meningeal exudation was found to contain several micro-organisms including the diplococcus intracellularis meningitidis of Weichselbaum. Microscopically evidences of inflammation were traced from the chiasma and along the optic nerve to the papilla of the inflamed eye. The essential pathological changes in the eyeball itself were neuro-retinitis along with diffuse inflammation of the uveal tract. Mr. Stephenson concluded that inflammation passed from the cerebral meninges along the optic nerve to the eyeball, probably by means of the perivascular lymph sheaths.

The following cases and card specimens were shown :—

Dr. J. ROWAN: Sections of the Healing Stump of an Optic Nerve four days after Enucleation.

Dr. J. HERN: (*a*) A case of Essential Shrinking of the Conjunctiva; (*b*) Persistent Pupillary Membrane; (*c*) case of Abnormally large Cornea and deep Anterior Chamber.

Mr. H. E. JULER: Retinal Detachment with (?) intraocular growth.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Indications for the Removal of the Uterine Appendages.

A MEETING of this society was held on June 14th, Dr. W. J. SMYLY, the President, being in the chair.

Dr. W. H. A. NEWNHAM (Bristol) showed a Uterine Myoma removed by Intraperitoneal Hysterectomy from a patient, aged 24 years.

Dr. G. ELDER (Nottingham) showed a Double Ovarian Dermoid Tumour.

Mr. J. FURNEAUX JORDAN (Birmingham) showed Specimens Removed by Vaginal Cœliotomy.

The discussion on a paper by Dr. MACPHERSON LAWRIE upon Indications for the Removal of the Uterine Appendages which was adjourned from the last meeting was opened by a communication from Dr. MACNAUGHTON-JONES, sen., who was unable to be present. He held that there was unanimity of opinion as to the necessity of removing the appendages in the case of (1) disease of the oviduct, suppurative, cystic, or other, destroying its integrity and obliterating its lumen; (2) in blood cysts both of the ovaries and Fallopian tubes; (3) in solid tumours of the ovary; and (4) in most cases of ectopic gestation. As to the large number of sufferers from reflex troubles and nervous conditions, in which gross changes might or might not be found in the genitalia, it had often been proved that the pathological changes found in the ovaries and tubes, though not apparently of great importance on examination beforehand, had been of a grave character, incurable in their nature and therefore wrong to leave unremoved. On the general question of the removal of the whole or part of the internal genitalia, such removal was not to be considered except (1) where other therapeutical steps had either been tried and proved valueless or the procrastination involved in resorting to them was both directly and indirectly injurious to the woman; and (2) when the risk of operation was less than that of non-interference.

Dr. C. H. F. ROUTH strongly opposed the removal of the uterine appendages, whether the inflammation was suppurative or not. In the former case the plan he advocated was aspiration of the tumour, followed by the injection of iodine. He considered that they had no right to remove the ovaries on account of pain, especially as oöphorectomy altered the frame of the woman's mind and predisposed to insanity.

Dr. G. ELDER (Nottingham) said that none of them doubted the propriety of removing the appendages for pyosalpinx, suppurating ovaries, ectopic gestation, and tumours, and some of them believed in removing the ovaries for myoma in certain cases. But there were grounds for discussion as to the propriety of dealing with non-suppurative diseases such as Dr. Lawrie had described in group "*a*." When the late Mr. Lawson Tait had the inspiration to remove the ovaries and tubes in the case of inflammatory conditions it was a great advance on previous methods. No doubt many ovaries and tubes were subsequently removed that ought to have been allowed to remain. Probably most of those present had removed ovaries which on after-consideration they would have allowed to remain. He was led to reconsider the matter by the fact that in some instances after the removal of the appendages the pain was no better than before. His own practice now in doubtful

cases was to examine the patient under an anæsthetic and, if necessary, make an exploratory incision, dealing with the appendages according to the condition found at the time.

Mr. E. STANMORE BISHOP (Manchester) took exception to some points in the paper—e.g., to the recommendation that a pyosalpinx should be tapped and drained, if by this was meant that the swelling should be aspirated by means of a trocar. A free incision was needed, otherwise the sac would fill up again. Dr. Lawrie had mentioned two classes of cases of myoma where he advocated oöphorectomy—when the myoma was small and the appendages were diseased, and when the patient was much weakened by hæmorrhage. In the first case he presumed that Dr. Lawrie removed the appendages because they were diseased and not on account of the myoma; in the second case, he would point out that the removal of the appendages was often insufficient to control the hæmorrhage. With regard to a second operation, his view was that this was always bad for the patient.

Mr. J. FURNEAUX JORDAN (Birmingham) agreed with the greater part of the paper. He did not think, however, that a conservative reaction could go too far. In one case of pyosalpinx he incised and washed out the tube with a good result. In another case of cystic ovaries he removed one ovary and dealt with the other ovary by ignipuncture and the patient bore a living child 12 months later. He held that the appendages should never be removed unless they were palpably diseased and for the determination of this point an exploratory incision was often valuable. He agreed with Dr. Lawrie's remarks about oöphorectomy for myoma and, contrary to Mr. Stanmore Bishop's views, he held that hysterectomy was easier after a preliminary oöphorectomy, for he had operated under those circumstances in three cases.

Mr. J. BLAND-SUTTON expressed his interest in Dr. Lawrie's paper and said that it was important to observe how much the operation of oöphorectomy had become limited in recent years. From the beginning of his surgical career he had always acted upon one rule—never to remove ovaries and Fallopian tubes unless there was very tangible evidence of disease in these structures. Increased experience had taught him to limit the removal of tubes and ovaries to two sets of conditions—viz., inflammatory lesions and tubal pregnancy. Under the title of inflammatory lesions of the uterine appendages he included chronic salpingitis, pyosalpinx, and hydrosalpinx, and also tuberculous salpingitis. These were the commonest conditions for which double oöphorectomy was required. The extreme frequency of gonorrhœal and post-partum endometritis among hospital patients was in striking contrast to its infrequency among private patients, and this he believed was due to the fact that the poorer harlots took less care of their genitals than the well-to-do courtesans; and that the wives of the poor did not receive the same careful obstetric nursing as the wives of the rich. He had never performed oöphorectomy for the cure of neurotic conditions and he discountenanced removal of ovaries in patients with dysmenorrhœa when there were no obvious physical signs. It was disappointing to find that such a progressive surgeon as Dr. Lawrie still practised the removal of ovaries for the relief of fibroids, but that operation, like the still more unsatisfactory one of double oöphorectomy for the relief of mammary cancer, was rapidly disappearing from the field of legitimate surgery. The results in Dr. Lawrie's series of cases were very satisfactory. Dr. Victor Bonney had drawn up a series of cases in which Mr. Bland-Sutton had performed abdominal oöphorectomy for inflammatory lesions and tubal pregnancy at the Chelsea Hospital for Women since he was appointed surgeon to that institution. The table contained 92 consecutive cases and there were no deaths in the series. This gratifying result was due to the maintenance of thorough asepsis, abstention from irrigation, and the substitution of a strip of sterilised gauze for the drainage-tube. Mr. Bland-Sutton requested that his table of cases should be appended to his remarks when they were published in the society's journal. His results in private practice had been equally successful, but he preferred to publish the table drawn up by an independent person, with the dates and initials of the patients operated upon in a public institution where anyone could examine the records.

Mr. F. BOWREMAN JESSETT thought that Dr. Lawrie's attitude had been misunderstood. It had been assumed that he advocated operation in all cases, whereas he specified that it should be restricted to cases in which other methods had failed. Dr. Mary Dixon Jones had shown that there were cases in which the ovaries presented no enlargement and yet were much diseased, and he imagined that some of Dr. Lawrie's cases came under this category. He thought that the plan advocated by Dr. Routh in the case of pyosalpinx was not without considerable risk.

Mr. SKENE KEITH remarked that he did not believe in removing ovaries from patients who were in perfect health. There was a condition of the ovaries to which no reference had been made, in which the ovary appeared to be healthy on the surface, but on cutting it open there was a thick capsule almost as hard as cartilage. With each recurrence of ovulation much pain must necessarily result and the patient became emaciated; if the general health of the patient was not thus affected it was not time to operate. He did not agree with Mr. Bland-Sutton as to oöphorectomy for myoma; if the whole of the ovaries were removed he would guarantee the cure of the bleeding.

Dr. FREDERICK EDGE (Wolverhampton) said that no doubt the results of conservative operations on the appendages had been disappointing in many cases but they had been equally gratifying in others, and the practical point was to find out in which cases it was well to try conservative methods. It had struck him that the cases where conservative plans had failed were much the same as those in which the removal of the appendages was not followed by full recovery—i.e., the uterus and other pelvic structures were implicated, and either radical removal of the uterus and adnexa should be performed or the case should be left to medical treatment. It was a rule with him to remove the appendages and not to try conservative operation in gonorrhœal cases; but Mr. Taylor had shown that many of these cases had a syphilitic basis, or at least alterative treatment would relieve them.

Mr. CHARLES RYALL pointed out that the tendency to the removal of the ovaries had diminished since it was realised that they had a function of internal secretion which had an effect on the whole system. He believed that oöphorectomy for myoma should be abandoned except in the conditions mentioned by Mr. Furneaux Jordan.

Dr. ARTHUR GILES thought the justifiability of operations such as those grouped together by Dr. Lawrie as class "*a*" must largely depend on their results. If a condition incapacitated a woman and prevented her from earning her living and an operation would restore her to health and usefulness he thought that Dr. Lawrie was right in saying that it was the duty of the surgeon to perform it. They required, however, to know more of the after-histories of these cases. Neurosis was a frequent cause of failure of these as well as of other operations, and he felt that in dealing with a neurotic patient no operation at all should be performed except as a matter of the most absolute necessity. He pointed out that oöphorectomy had failed to relieve hæmorrhage in cases of myoma, not only owing to a portion of ovary being left behind, but also because the operation had been done in some cases where the bleeding was due to a myoma that had become polypoid. When oöphorectomy was contemplated he thought that the cavity of the uterus ought always to be first explored to eliminate this source of failure. The cases of myoma requiring oöphorectomy were now, in his opinion, very few.

Dr. MACPHERSON LAWRIE briefly replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases, &c.—Blood-pressure in Sleeplessness and Sleep.—Origin, Development, and Structure of the Umbilical Cord.

THE eighth ordinary meeting of this society was held on June 6th, Dr. A. G. MILLER, the President, being in the chair.

Dr. JAMES CAMERON exhibited a woman, aged 50 years, suffering from Adiposis Dolorosa; a large epigastric pendulous tumour was present.

Mr. C. W. CATHCART exhibited:—1. A boy on whom he had performed Laparotomy for Intestinal Obstruction caused by

an accumulation of foreign bodies in the lumen of the tube, together with the pressure of a calcareous tuberculous gland on the outside. The obstructive material had evidently been eaten in an Italian salad and had undergone no digestion. The boy was not seen until three days subsequent to the onset of obstruction and when operated upon was in a very collapsed condition. 2. A woman from whom he had Excised a Portion of Gangrenous Bowel resulting from a Strangulation of a Femoral Hernia.

Mr. C. W. CATHCART also showed a Surgical Operating Case made in the shape of a box of polished zinc and having a waterproof covering. Such a case was much preferable to the ordinary surgical bag which could not be sterilised. In this case various parts (such as the lid, one side, covers of boxes, &c.) were removable and formed trays for holding the instruments in antiseptic solutions. All the parts were easily sterilised and, moreover, the case was comparatively cheap and compact.

Mr. C. W. CATHCART also showed a portion of the Sigmoid Flexure removed on account of a new growth.

Dr. LEWIS C. BRUCE read a paper on the Blood-pressure in Sleeplessness and Sleep. The instrument employed to estimate the arterial blood-pressure was Barnard and Hill's sphygmometer and the statement of Hill that "the normal general arterial pressure in the horizontal posture equals about 110 mm. of mercury" was assumed to be correct. The first points investigated were: (1) Were there any unusual conditions of blood-pressure which were associated with sleeplessness in mental disease? (2) What changes occurred in the blood-pressure when sleep was induced in these cases by drugs? There were two classes of cases met with: (1) conditions of sleeplessness with high blood-pressure—i.e., above 130 mm. of mercury; and (2) sleeplessness with a low blood-pressure—i.e., below 110 mm. of mercury. The drugs employed to promote sleep were the following: paraldehyde, sulphonal, trional, and bromide of potassium. In the group of cases with a high blood-pressure paraldehyde in large doses (two drachms) was found to be the most certain sleep producer; sulphonal came next in power, and then trional. Bromide of potassium was found to be unsatisfactory. When sleep was induced by any of these drugs the blood-pressure always fell to, or even below, 110 mm. of mercury during sleep. In the second group of cases, sleeplessness with low blood-pressure, paraldehyde in large doses of two drachms acted as a cerebral excitant, tended to raise the blood-pressure, and satisfactory sleep was never obtained. After small doses, however—from 15 to 30 minims—these same patients slept well. In this second class of cases trional in 20-grain doses and then sulphonal were the most satisfactory drugs. Trials were also made of erythrol tetranitrate in doses of one grain per day in cases of insomnia with high blood-pressure, the object being to induce sleep by artificially lowering the blood-pressure. Of nine cases three were immediately and permanently benefited, three were very temporarily relieved, and the remaining three cases were not affected by doses of even two grains per diem. A second series of observations was made upon convalescent patients in order to throw light upon the following questions. 1. Was sleep possible with blood-pressures of 130 mm. of mercury or higher? 2. What relation did the morning blood-pressure bear to the evening pressure when a person was sleeping well? 3. Were there any differences in the blood-pressure of the same person asleep under the action of drugs and during natural sleep? The results were as follows. 1. Sleep was possible with high blood-pressures, but the pressure always fell to 110 or about 110 mm. of mercury after the condition of sleep was established. 2. The general blood-pressure was, as a rule, higher in the morning than in the evening in a state of health and the reverse of this held good in some cases of sleeplessness. 3. In the drug sleep induced by paraldehyde the blood-pressure fell at its lowest about 10 mm. of mercury below the habitual blood-pressure of the same person when sleeping naturally. As the effect of the drug passed off the blood-pressure rose and eventually passed to the blood-pressure habitual to that person in natural sleep; in short, drug sleep passed in some cases into natural sleep.—The paper was discussed by Dr. T. S. CLOUSTON, Dr. JAMES FOULIS, Dr. CLAUDE B. KER, Dr. T. RONALDSON, Mr. C. W. CATHCART, and the PRESIDENT, and Dr. BRUCE replied.

Dr. JAMES FOULIS read a paper on the Origin, Development, and Structure of the Umbilical Cord and illustrated it with lantern slides. The object of the communication was to show that the cord itself had no covering of amnion at any period of its existence and that the usual statements in the text-books that the cord had a tubular investment of amnion were entirely wrong, the truth being that the cord proper was always within the amniotic sac and was a tubular prolongation of the somatopleure round the collapsed and shrivelled yelk sac. Numerous micro-photographs of sections of embryos from the deer and sheep were shown in order to illustrate the development of the umbilical cord. The amnion was everywhere continuous with, and an extension of, the somatopleure; and as the somatopleure itself was formed by the union of the epiblast with the somatic mesoblast the amnion was itself an extension of these two membranes and in the micro-photographs the amnion could easily be seen as a double-layered membrane as it passed round the dorsum of the embryo. Before the umbilical cord had an existence as such the amnion could be traced as an outgrowth from the sides of the *bauchstiel* of His, and from the somatopleure around the large umbilical foramen, now widely open. In the early embryo of the deer and sheep there was at first no such structure as the umbilical cord, but the vascular connexion between the embryo and the uterus was in the form of the ventral string of the *bauchstiel*. This *bauchstiel* was an outward growth of mesoblast from the caudal end of the embryo towards the chorion. In its mesoblastic substance were to be found the two large umbilical veins—two umbilical arteries with the allantois which might be traced as a tubular outgrowth from the cloacal end of the primitive intestine and lined with hypoblast. This *bauchstiel*, as the analogue of the true umbilical cord, had a great share in the formation of the cord itself. To trace out the formation of the umbilical cord from the *bauchstiel* was a difficult thing, unless the relation of the somatopleure to the amnion was constantly remembered. Transverse sections of the *bauchstiel* showed that the somatopleure folds, of which for the most part it consisted, gave out on both sides the amnion membrane by simple extension of the somatopleure substance. The caudal fold of the somatopleure gave off the amnion just in the same way as the lateral folds of somatopleure gave it off. The whole dorsal surface of the embryo was thus inclosed within the amnion sac, which was thus attached to the sides of the *bauchstiel* and to the margins of the large umbilical foramen round the collapsing yelk sac. It was important to notice that at the caudal end of the embryo the amnion was attached to, or came off from, the somatopleure at a spot between the under surface of the *bauchstiel* and the anal orifice. At first the *bauchstiel* or ventral string occupied an almost horizontal position as an extension of the caudal end of the embryo; but as soon as fluid began to accumulate within the amnion sac the *bauchstiel* was gradually raised up to an almost vertical position, the amnion coming off from its lateral margins being continuous with the amnion of the lateral somatopleure folds. The distal portion of the allantois gradually collapsed, while that part within the body cavity gradually became the urinary bladder. As a result of the distension of the amniotic sac in all parts by fluid the amnion itself was gradually lifted off the embryo at all parts except at the line of its attachment to the sides of the *bauchstiel* and to the somatopleure folds round the umbilical foramen, which was now closing in round the shrunken yelk sac. The somatic mesoblastic surfaces of the somatopleure were everywhere opposed to each other, and as they actually came in contact they adhered to each other round the yelk sac, thus shutting off the cœlom or body cavity from the false amnion sac. It was most important to bear in mind that this closing in of the somatopleure and the adhesion of its opposed mesoblastic surfaces took place only within the amnion sac, which was thus continuous with, and an extension of, the somatopleure tube thus formed round the yelk sac. No amnion at any time covered the cord or somatopleure tube thus formed, but it was always continuous with this somatopleure tube or umbilical cord at its distal end, and when the true amnion sac became more and more distended the mesoblastic surface of the amnion at last became opposed to the mesoblastic surface of the false amnion, to which it adhered slightly. The amnion thus invariably covered the fœtal surface of the placenta, from which it could be easily stripped off, but, of course, it could not be stripped off the umbilical cord because it was an extension of, and part of, the cord itself.—Dr. D. BERRY HART and others took part in the discussion which followed and Dr. FOULIS replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Cerebro-spinal Meningitis.

A MEETING of this section was held on May 18th, Sir J. W. MOORE, the President, being in the chair.

Dr. H. C. DRURY read a paper on Cases of Epidemic Cerebro-spinal Meningitis. After a brief reference to the past history of the disease from its first recognition in Geneva in 1805 he discussed its pathology and then the etiology, quoting various authorities on the questions of its contagiousness and mode of dissemination. The symptoms more or less important in, or peculiar to, this form of meningitis were then taken *seriatim* and fully discussed, and the means of certain diagnosis by the method of "lumbar puncture" and bacteriological examination were described in detail. Dr. Drury then related eight cases which he had met with in Cork-street Fever Hospital. The first patient, a man, aged 20 years, was admitted on Nov. 18th, 1899, and after a prolonged illness he recovered. Of the other seven patients four died. In only one case was there a rash—a feature so typical of the great Dublin epidemic of 1866–67—and this rash was not petechial, but pustular, with hæmorrhage into the pustules, and it came late in the disease. In all the cases the disease commenced suddenly with rigidity of the neck or actual retraction of the head, and in some cases opisthotonos; all of the patients had deafness in some degree, pain in the head and limbs, and Kernig's sign. One case was mentioned, though not included in the above eight cases, which without bacteriological examination could not have been diagnosed. It was the case of a man, aged 50 years, who had had pneumonia and was up about the ward convalescent for a week when he suddenly developed most marked symptoms of acute meningitis and died on the fourth day. Post-mortem examination revealed pus all over the meninges and a fungous growth on one of the aortic valves. This vegetation and the pus yielded pure cultures of pneumococcus and not the diplococcus intracellularis, though the pathologist (Dr. O'Sullivan) was looking for the latter, being unaware of the previous history of pneumonia.

Dr. A. R. PARSONS read a paper on Cerebro-spinal Meningitis, which was discussed with Dr. Drury's paper.

Dr. N. M. FALKINER presented a table showing the Number of Deaths in the Dublin Registration Area from all forms of Meningitis in the years 1895–1900. Taking the years 1895 to 1899 inclusive the average number of deaths from all forms of meningitis for the first 19 weeks of each year was 102·6, but in 1900 the number of deaths in a corresponding period was 182·0 and the increase embraced ordinary meningitis, tuberculous meningitis, cerebro-spinal meningitis, hydrocephalus, and secondary meningitis. All forms of meningitis should be treated as zymotic diseases. Sir Charles Cameron had adopted the proper course in making meningitis a notifiable disease.

The PRESIDENT remarked that that was the first occasion on which meningitis had been made a notifiable disease. At the Meath Hospital they had had 11 cases with three deaths and eight cases were still under treatment. This showed that the mortality was not at all so high as in the epidemic of 1867. The first case was that of a girl, aged three years, who was admitted on Feb. 24th and who recovered. As to treatment, in the present epidemic he had found that the most successful measures were leeching behind the ear and the repeated application of small blisters behind the ear. The agonising headache was relieved by a combination of acetanilide, caffein, and sodium bicarbonate.

Dr. O'SULLIVAN described the post-mortem appearances in some of the cases. The fluid obtained by lumbar puncture was turbid but colourless. The pus in the spinal region lay in one case altogether outside the spinal dura, the cord being quite firm and apparently healthy. In the other cases it lay in the meshes of or underneath the pia mater and the cord was softened. In the brain the pus was in all cases in or under the pia-arachnoid. The distribution of the pus on the surface of the brain was very symmetrical. In all cases the cerebro-spinal fluid was greatly increased in quantity and was turbid, but it was not bloody or (to the naked eye) purulent. The diplococcus intracellularis was found in the turbid fluid and in the pus, usually in pure culture. It grew best on Löffler's serum, but also on glycerine agar, and less actively on ordinary agar. In the pus the organisms were seen in the pus cells, usually in small numbers, as diplococci with their adjacent surfaces flattened, varying a good deal in size and depth of staining. They did not stain by Gram's method. Inoculation experiments were unsuccessful.

Professor E. J. MCWEENEY said that the first case which had come under his notice was that of a schoolgirl who died in the Mater Misericordiæ Hospital early in February. There was an accumulation of thick mucoid pus symmetrically placed in the posterior cornu of each lateral ventricle. Microscopical examination of the material at once revealed the intracellular diplococcus. In all the cases which he had subsequently examined post mortem the same features recurred: occurrence of actual suppuration, the pus being very tough and mucoid; symmetrical disposition of the lesions on each side of the brain; distension of the lateral ventricles with turbid fluid; implication of the sides and back of the cord; and paucity of the intracellular cocci in the fibrinous exudation on the membranes. In working with cultures of the organism care should be exercised, for three German observers had all contracted severe rhinitis and in the case of one there was some stiffness of the neck as well. This would seem to indicate a slight affection of the spinal meninges and if the observation were accurate it would serve to show that the path by which the infective matter enters the cranial cavity is through the nose—possibly then through the cribriform plate. There was a disease of horses, known in Germany as Borna's disease, in which the essential lesion was a cerebro-spinal meningitis. Intracellular cocci had been found in the pus and it seemed quite possible that the disease might prove to be identical with human cerebro-spinal meningitis. He had heard that numerous cases had lately been observed in horses about Dublin and this was of interest in connexion with the present epidemic amongst human beings.

Dr. TRAVERS SMITH, Professor E. H. BENNETT, Dr. J. KNOTT, and Dr. J. CRAIG also discussed the papers.

BRITISH ORTHOPÆDIC SOCIETY.—A meeting of this society was held at the Orthopædic Hospital, Bristol, on May 19th.—Mr. A. H. Tubby read a paper on the Treatment of Spinal Abscess. He advocated the opening of the abscess as soon as it approached the surface by two incisions as far apart as possible; its thorough evacuation, and scraping or rubbing of the lining membrane; irrigation with iodoform solution, paroleine, or menthol; and closure of the incisions.—Mr. Noble Smith advocated incision and drainage and frequent irrigation.—Mr. Jackson Clarke, Mr. W. H. Harsant, and Mr. J. Ewens also spoke, and Mr. Tubby replied.—Mr. T. Carwardine opened a discussion on the Treatment of Severe Congenital Equino Varus. He divided cases into four groups: (1) severe at birth, (2) severe in childhood, (3) in adolescents, and (4) in adults. Treatment should begin early. Constant personal attention was required and persistence in after-treatment. In rigid cases of the third and fourth degrees manipulation alone was not enough. Tenotomy and the gradual method with apparatus needed patience and perseverance for six or twelve months. Wrenching was suitable in patients aged five years and upwards, but it was unsurgical and its results were temporary. Free subcutaneous section was too severe for young children. The skin was usually too tight to allow of correction. Phelps's operation was therefore better. With respect to tarsotomy and tarsectomy he said that Phelps's original operation did not correct the deformity of the bones, and it made a large wound which took a long time to heal with subsequent contraction. The result of astragalectomy was immediate and little after-treatment was needed, but it had ended in suppuration and amputation in some cases. Cuneiform tarsectomy corrected the varus deformity and saved time and trouble and expensive after-treatment, but it was a mutilating method and it prevented the gradual method being employed afterwards. It shortened the foot and destroyed the arch, interfered with growth, and left a stumpy inelastic foot. It treated the effect on the outer side rather than the cause on the inner side of the foot. Phelps's latest operation had the following advantages. It saved time; bony mutilation was slight, plantigrade progression was immediate; the foot was not shortened, nor was its elasticity impaired; the ankle and tarsal joints were not interfered with and their mobility was

preserved; being a less severe form of tarsectomy it was applicable to younger patients; it could not appreciably interfere with growth; and it treated the foot at the point of anatomical deformity.—Mr. Ewens, Mr. Little, Mr. Thomas, Mr. Jackson Clarke, Mr. Tubby, Mr. Noble Smith, and Mr. Harsant took part in the discussion, and Mr. Carwardine replied.—Cases were shown by Mr. Ewens and Mr. A. F. Blagg.

Reviews and Notices of Books.

Ulcer of the Stomach and Duodenum and its Consequences. By SAMUEL FENWICK, M.D. St. And., F.R.C.P. Lond., Consulting Physician to the London Hospital; and W. SOLTAU FENWICK, M.D., M.R.C.P. Lond., Senior Physician to the London Temperance Hospital, Physician to the Evelina Hospital for Sick Children. London: J. & A. Churchill. 1900. Pp. 392. Price 10*s.* 6*d.*

THE morbid condition known as ulcer of the stomach is so frequently met with and its diagnosis and treatment present so many points of doubt and difficulty that a monograph on the subject from such a well-known authority on diseases of the digestive tract as Dr. Fenwick will be sure of a welcome from medical men. He has been assisted in the preparation of the book by his son, Dr. W. Soltau Fenwick.

The work is divided into four parts. The first part deals with the Pathology and Etiology of Gastric and Duodenal Ulcer. The chapter on Morbid Anatomy contains a very full account of the various changes found in the walls of the stomach when ulceration has occurred, and numerous reproductions of photographs of morbid specimens of ulcer of the stomach materially add to the value of the descriptive letter-press. The authors have taken considerable pains in the elaboration of their conclusions respecting the morbid anatomy; the material was derived from the post-mortem records of 1015 cases of ulcer of the stomach and of 130 cases of ulcer of the duodenum. In order to avoid the errors that are apt to arise from the collection of isolated examples of the disease the authors wisely confined themselves to the records of hospital cases. One of the principal features of the analysis of the cases is the distinction which is made between the acute and chronic forms of the complaint as regards their origin, appearances, and modes of termination. Some of the points drawn attention to in this respect are interesting. For instance, the relative frequency of acute and chronic ulcers in different regions of the stomach. Out of 39 cases of acute ulcers 13 (33·3 per cent.) occurred in the pyloric zone, whilst out of 70 cases of chronic ulcers no less than 53 (75·7 per cent.) were found in that region.

The chapter on the Results of Ulceration contains a large amount of useful information. Attention will naturally be paid to the remarks on hæmorrhage and perforation. Considering the wide area of destruction wrought by a chronic ulcer and the extreme vascularity of the stomach, it seems surprising at first sight that only about 18 per cent. of the fatal cases die from hæmorrhage. The authors therefore remind the reader that not only is liability to bleeding minimised to a great extent by obliterative inflammation and thrombosis of the vessels in the immediate neighbourhood of the disease, but that any rent in their walls is rapidly closed by the contraction of the muscular coat and the coagulation of the blood at the seat of puncture. It is probable, therefore, that in every case of fatal hæmorrhage one or more of the following conditions will be present: (1) non-obliteration of the vessel previously to its erosion; (2) insufficient contractility of its muscular coat; (3) deficient coagulation of the blood; and (4) an abnormally high tension in the arterial or venous system of the organ.

The effects of perforation of the stomach and duodenum are treated in an able manner. The pathogenesis of ulcer of the stomach has always been open to doubt. Many theories have been from time to time advanced, but no single one has been universally accepted, and the remark of the late Dr. H. Gawen Sutton in his lectures to the students at the London Hospital will probably commend itself to the majority of practitioners: "When asked, 'What is the cause of simple ulcer of the stomach?' say, 'I don't know.'" The authors of the work under consideration enter fully into the many views which have been expressed, for there are few subjects in pathology that have given rise to more discussion than the mode of production of a gastric ulcer; and finally they state that although our knowledge concerning the causation of gastric ulcer is still very imperfect certain facts warrant us in coming to the following conclusions. An acute ulcer of the stomach or duodenum may either appear as a primary affection or develop during the course of some organic or constitutional affection. Acute primary ulceration often commences as a hæmorrhage into the inner coats of the stomach during the hyperæmia which takes place at each menstrual epoch and under other conditions. Chronic ulcer of the stomach or duodenum may follow the acute disease in young women or commence by the superficial digestion of a portion of the mucous membrane, where vitality has been diminished by certain conditions, such as obliteration of a nutrient vessel by atheromatous, fatty, lardaceous, or syphilitic disease, chronic inflammation of the mucous and submucous tissues, local anæmia of the gastric wall from pressure, or fibroid or fatty degeneration of the mucous membrane such as occurs spontaneously after the age of 40 years.

The second part of the book contains a description of the symptoms, varieties, and treatment of acute ulceration of the stomach and duodenum. The separation of gastric ulcer into two varieties—acute and chronic—is certainly to be commended, as without this classification confusion has arisen in differentiating many clinical varieties of the complaint according to the exceptional prominence of some particular symptom. If this pathological basis be accepted the clinical sub-division is unnecessary. The account of the symptomatology and of the treatment is clearly and concisely written, and the style adopted is one calculated to attract the attention of the reader. The surgical treatment of perforation has been frequently carried out and the authors have collected the statistics of a large number of cases so treated. The results show that the operation depends for its success or failure upon three factors: 1. The time which is permitted to elapse between the occurrence of the perforation and the performance of laparotomy. The earlier the operation is performed the greater will be the chance of its success. 2. The treatment of the hole in the stomach—it is absolutely necessary that the perforation should be closed. 3. The care with which the peritoneum is cleansed. After a careful study of the reported cases the authors believe that in course of time the early performance of laparotomy, combined with skilful closure of the perforation and thorough cleansing of the peritoneum, will render the surgical treatment of perforated gastric ulcer one of the most successful operations of its kind.

The third part of the book deals with the symptomatology of the ordinary chronic ulcer. Five varieties are differentiated and the difficulties involved in their prognosis, diagnosis, and treatment are discussed. The classification is based on clinical grounds, according to the special predominance of some particular symptom such as pain, vomiting, dyspepsia, hæmorrhage, and cachexia. The chapter on Diagnosis is particularly well designed, and the introduction of tables summing up the points to be relied upon in differential diagnosis is to be commended.

The final portion of the volume is devoted to the different sequelæ of ulceration. In most text-books these have hitherto received less notice than they deserve. Special attention is directed to the effects of perigastric adhesions, to the deformities of the stomach that ensue from the cicatrisation of the ulcer, and to the various internal fistulæ. A full account is also given of such subjects as perigastric and periduodenal abscess, tetany and other nervous disorders, cancer, tuberculosis, pernicious anæmia, gastric catarrh, and hypersecretion. With regard to the latter complaint the belief is expressed that the excessive secretion of gastric juice is only a reflex result of the irritation produced by the presence of the ulcer, and reasons are given for believing that the so-called "disease of Reichmann," or gastrosuccorrhœa, instead of being a primary functional disorder of the stomach, is merely a consequence of the retention of the gastric contents in certain forms of pyloric obstruction. The arguments adduced in favour of this view are sound and we believe the authors' theory to be the correct one.

We were much interested in a study of this work and we can cordially recommend it to the attention of our readers.

Twentieth Century Practice: an International Encyclopedia of Modern Medical Science by Leading Authorities of Europe and America. Edited by THOMAS L. STEDMAN, M.D., New York City. In 20 Volumes. Vol. XIX.—Malaria and Micro-organisms. London: Sampson Low, Marston, and Company, Limited. 1900. Price 30s.

THE ardent way in which researches of a subtle, refined, and minute character have been pursued of late into all that relates to malaria and malarial disease, the discoveries that have been already made, and the promise of others which have yet to come, have combined to make up one of the most interesting—we might almost say romantic—stories in the history of scientific investigation on a miniature scale. The results, moreover, of our rapid progress in this direction, interesting and suggestive as they are, have this practical advantage—that they are not merely circumscribed within the limits of the scientific terms in which they are expressed, but have a very practical significance which may turn out to be capable of wide application and of the utmost value to humanity.

Having once got hold of a clue to the explanation of the nature and causes of the varied phenomena of malarial fever in man, the meaning of which had hitherto seemed so puzzling and mysterious, inquirers were naturally impelled to follow it up to a logical conclusion by tracing out the life-history of the parasitic micro-organism which is at the root of the whole matter, in order to see how it effected an entrance into the human system and, further, how this could be practically prevented.

Since Laveran in 1880 discovered the malarial parasite and opened out, as it were, an almost new zoological field of observation, the subject has been keenly investigated by numerous scientific workers, among whom the names of Golgi, Marchiafava, Bignami, Grassi, and Celli, of the Italian school, and of MacCallum, Manson, Ross, Koch, and others, will at once occur to such of our readers as have interested themselves in this special branch of natural history. More light and experimental observation are now wanted to determine the nature, and still more the extent, of the rôle played by the mosquito as a vehicle for the conveyance and spread of the malarial parasite.

The simple enumeration of the names of the contributors to this volume dealing with malaria and micro-organisms suffices to show that the subjects have been entrusted to worthy hands. Their names are Professor Bignami and Professor Marchiafava of the University of Rome, Professor Simon Flexner of the University of Pennsylvania, and Eugene L. Opie of the Johns Hopkins University at Baltimore, the section on Micro-organisms being by Professor Flexner. The contributions on Malaria by Marchiafava and Bignami are, it should be added, illustrated by a number of excellent plates. There is no need, even were it possible within the limits of a review, to deal with all the points connected with malaria. These are discussed with an elaboration of detail which leaves little to be desired. After a brief historical sketch and a reference to the parasitology of the subject, the life cycle of the malarial parasite in man in connexion with the different forms and varieties of malarial fever and the life cycle of the parasite in mosquitoes, the hæmosporidia of birds and mammals, the mode of entrance of the parasites into the human organism, the malarial environment and the general and special pathology of malarial disease are severally discussed, and a description of the varieties, complications, and sequelæ of malarial disease from a clinical and therapeutical point of view follows.

Biological researches in relation to health and disease have revolutionised our views in many respects all along the line of medical science, but this has been especially the case in regard to malaria and malarial disease. The danger now is, perhaps, lest the rising of a new and possibly partial truth should be accompanied by the setting or obscuring of some older ones. The progress of discoveries regarding the malarial parasite has been so rapid that we can quite appreciate the force of what the authors say in their introduction—namely, that it has been found necessary to re-write entire sections of their contributions and to change others. Those on Parasitology and Etiology, in particular, have had to be greatly modified as a result of the latest researches. A special section has been devoted to the subject of Tropical Malaria, and the consideration of Hæmoglobinuria has been included in the treatise. There are some descriptions of the rarer and more pernicious forms of climatic or malarial fever with which probably only those medical officers who have served a good deal abroad are acquainted. Some of the most acute and severe attacks of these forms of fever resemble Asiatic cholera so closely that they might easily be mistaken for that disease.

We may refer our readers to Dr. Patrick Manson's lecture on Malaria and the Malarial Parasite, published in THE LANCET of May 19th, 1900 (p. 1417) for much interesting and instructive information as to the position which the subject holds at the present time.

We have left ourselves very little room to speak of the section devoted to Micro-organisms, contributed by Professor Simon Flexner of Philadelphia, which occupies nearly 300 pages of the present volume. The article takes a comprehensive view of the subject and is very carefully and lucidly written and illustrated.

Speaking generally of the nineteenth volume of the Twentieth Century Practice of Medicine we may say that it forms an admirably executed treatise on the subjects with which it deals. Its contributors are men of high scientific repute and are well qualified for the task which they have undertaken, and they seem to have done their best to make the fulfilment of it as complete and up-to-date as practicable. The volume will remain for a long time a valuable book of reference in connexion with the subjects of which it treats.

Atlas und Grundriss der Lehre vom Geburtsakt und der Operativen Geburtshilfe. (*Atlas and Outlines of Labour and Operative Midwifery.*) By Dr. OSCAR SCHAEFFER. Fifth enlarged edition. With 16 coloured plates and 139 illustrations. Munich: T. F. Lehmann. 1900. Pp. 107. Price 8 marks.

THIS book consists of two parts with an atlas appended. The first part treats of the mechanism and the management of labour and the second part of the various obstetrical

operations. The mechanism of labour is well described and the author has happily combined the theoretical and clinical portion, so that at the end of the description of each of the stages in the mechanism the student is told what conditions he would find present on making an examination at that particular time.

The first chapter deals with the so-called natural presentations—viz., the vertex, the face, and the breech. In the second chapter abnormal varieties of the natural presentations are described, such as Naegele's and Litzmann's obliquity in vertex presentation, transverse position of the head in vertex and face presentations, and spontaneous evolution in shoulder presentations. Unnatural presentations—e.g., cross and shoulder and other varieties—are considered in Chapter III. In the second half of the book the various obstetrical operations with their indication and methods of performance are described. The atlas consists of some 120 drawings which serve as an excellent series of illustrations to the text, in which constant reference is made to them. The coloured plates, which have been drawn from a study of frozen sections and of the conditions actually met with at the bedside, are good and accurate, as are also the illustrations in the letterpress. The illustrations in the atlas can hardly be considered artistic and, indeed, in some cases they are not anatomically or clinically accurate. They are, however, really not much more than diagrams and they fully serve their purpose as diagrammatic illustrations of the various points discussed. A little more care might have been expended upon the correction of the proofs. Misprints are frequent and all the references in the text to the figures in the atlas after about figure 60 are erroneous. The book has reached a fifth edition in Germany and contains a greater amount of information upon the subjects of which it treats than many a larger and more pretentious work.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on June 14th, the President, Sir WILLIAM MAC CORMAC, Bart., K.C.V.O., being in the chair.

The PRESIDENT submitted a list of persons of distinction to whom the Centenary Committee recommended that invitations to the Centenary dinner should be sent. The list was approved. The following examiners were elected:—

Elementary Biology.—P. T. Bowman Beale, F. G. Parsons, T. W. Shore, and T. G. Stevens.

Anatomy under the Conjoint Board.—Stanley Boyd, W. Bruce Clarke, A. Robinson, and A. Thomson.

Physiology under the Conjoint Board.—J. Rose Bradford, G. A. Buckmaster, and L. E. Hill.

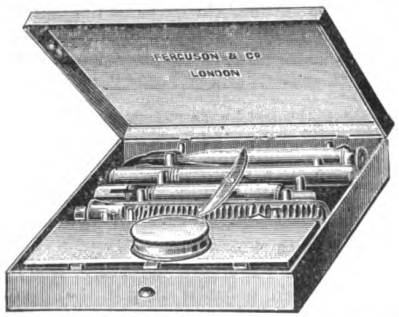
Anatomy for the Fellowship.—J. Ernest Lane, B. G. A. Moynihan, F. G. Parsons, and A. H. Young.

Physiology for the Fellowship.—T. G. Brodie, W. D. Halliburton, D'Arcy Power, and W. H. Thompson.

Midwifery under the Conjoint Board.—W. R. Dakin, W. S. A. Griffith, A. H. N. Lewers, and H. R. Spencer.

Diploma of Public Health.—Part I.: Christopher Childs. Part II.: S. A. M. Copeman.

INTERNATIONAL CONGRESS OF ELECTROLOGY AND MEDICAL RADIOLOGY.



THE Organising Committee of the above Congress wish to inform those who purpose to attend the Congress that a reduction of 50 per cent. will be made for their tickets on the following French railway systems—namely, those of the west, the north, the east, the Paris-Lyons-Mediterranean, the Orleans, and the State. Reductions varying with the length of the journey will also be granted by the Italian railways, of from 30 to 50 per cent. Those who are going to attend the Congress and who desire to avail themselves of these privileges are requested to apply to the General Secretary, M. Doumer, 57, Rue Nicholas-Leblanc, Lille, before July 1st, 1900.

The committee also desire to inform intending members of the Congress that their tickets of membership confer upon them the right of free entry to the Paris Exhibition as long as the Congress lasts.

New Inventions.

AN ASEPTIC VACCINATION CASE.

THE illustration represents an aseptic vaccination case made for me by Messrs. Ferguson and Co., of Giltspur-street, London, E.C., which I think might be useful to public vaccinators, as it fulfils the requirements of the last Vaccination Act and it is so small that it can be carried in the

waistcoat pocket. The outside measurements are—3¼ inches by 2¾ inches by ¾ inch. The contents are—(1) spirit lamp, (2) tube of one-grain soloids of mercuric iodide (Burroughs, Wellcome, and Co.) for cleansing the skin, (3) aseptic vaccinator, (4) metal case for lymph tubes, and (5) blower. The vaccination pads can be carried in a separate case.

CHARLES CORBEN, M.R.C.S. Eng., L.R.C.P. Lond.
Caldicot, Chepstow.

A PORTABLE SPITTOON.

THE spittoon, three views of which are given in the accompanying illustrations, has been designed by Mr. W. Harrison Martindale of No. 10, New Cavendish-street, W., and is intended for the use of phthisical patients whose sputum is liable to disseminate the disease unless special precautions are taken. As will be seen, the spittoon is made in two separable parts, the larger one being the container and the

other one consisting of the funnel and lid. Being entirely of sheet metal it has a neat appearance, is not liable to be injured, and can be readily cleaned and sterilised by boiling. It is of a convenient size for the pocket, being three and a quarter inches high and two and three-quarter inches wide, or it may stand on a table beside the patient's chair or bed. The lid will, of course, generally be closed, but can be easily raised with the thumb of the hand which holds the spittoon. Some disinfectant should be used in the spittoon, and for this purpose bottles containing small tablets of thymol are supplied. The price of the spittoon is 6*s.* 6*d.*

THE LANCET.

LONDON: SATURDAY, JUNE 23, 1900.

A CASE which was tried this week in London before Mr. Justice PHILLIMORE and a common jury affords a striking example of the dangers which beset a medical man in the performance of his duty—dangers, moreover, which he cannot avoid save by shirking responsibilities not only towards his patients but towards the public at large. The action was brought by a man named SOPER, employed as a coachman, against Dr. J. H. GIBSON and Dr. W. M. YOUNG (practising in partnership in Maida-vale) under the following circumstances. The plaintiff consulted Dr. GIBSON who was medical officer of a club of which the plaintiff was a member. He was in a state of great mental depression because his wife had become pregnant, and the responsibilities of the future alarmed him. At the same time, according to the evidence of the two defendants, the wife of the plaintiff informed them that her husband had threatened to murder both her and her children and that "he had made up his mind to end it." One of the defendants, Dr. YOUNG, enjoyed the peculiar advantage in dealing with such a case of 15 years' experience in a county asylum. He went to the plaintiff's house and carefully examined him, when the plaintiff said, among other things, that he "heard voices which prevented him from sleeping." Dr. YOUNG, satisfied as to his condition and finding the wife still alarmed, thereupon himself communicated with the relieving officer, who eventually removed the plaintiff to the lunacy ward of the workhouse infirmary. From this institution SOPER was, according to his own evidence—which does not appear to have been supported by that of any medical man connected with the workhouse or of any other person—discharged as sane after three days' detention. He brought his action in respect of this detention, alleging that it was due to professional negligence on the part of the defendants that he had been sent to the lunacy ward of the workhouse and claiming as for "false imprisonment." In answer to the plaintiff the two defendants gave their version of what occurred, while Dr. J. F. WOODS (medical superintendent of the Hoxton House Asylum) and Mr. W. RAYNER (visiting medical officer to the Marylebone Workhouse) gave testimony in corroboration. Their evidence was to the effect that the facts as stated by the defendants showed that the case was one of suicidal mania and that the defendants had acted most properly and in the plaintiff's interest, while they further explained to the jury the possibility of rapid recovery from acute suicidal mania. Dr. WOODS cited an instance that had come under his personal observation in which a patient so affected became sane after two days' confinement. The case, as summed up to the jury by Mr. Justice PHILLIMORE, resolved itself into the answer to a comparatively simple question—whether the two medical gentlemen who were brought to the court as defendants, in coming to the conclusion that the plaintiff was in a dangerous state and in communicating with the relieving officer, had acted negligently. To this the jury found the only answer that 12 sensible citizens could find, and their verdict for the defendants relieved Dr. GIBSON and Dr. YOUNG of the danger of being mulcted in damages. The verdict was endorsed by a judgment in behalf of the defendants "with costs." This means that of their expenses in defending the suit a portion, cut down to a minimum by the taxing master, will be due to them from the plaintiff who may or may not be able to pay them.

The medical aspects of the case require no discussion. At the time when SOPER left the workhouse infirmary he may have been perfectly sane without this in any way affecting the question of his condition when Dr. YOUNG examined him, as to which we have that gentleman's opinion, and also the evidence of a letter from the plaintiff in which he wrote: "Fate is against me ..... future happiness and good health seem out of the question for me," clearly showing his melancholic condition. But the story forms another example of the extraordinarily difficult position that is occupied by the medical man in affairs of this sort. Any medical man may at any time be invited to give an opinion upon the question of a man's sanity. If he honestly believes that there is danger in allowing the patient freedom of action he has one duty only, which is to declare that opinion and give effect to that opinion. By doing this he becomes directly responsible for the confinement of the person whom he believes to be insane and may be subjected to the inconvenience, anxiety, and pecuniary loss inseparable from an action at law when the person whom he has certified as a lunatic finds himself at liberty. This is because there exists no means of testing in such an action the genuineness of the plaintiff's claim until it is brought into court with all the costly accompaniments of solicitors, counsel, witnesses, and court fees, and with the further inevitable circumstances, of great consequence to medical men, of waste of time and a publicity of an unenviable sort. The public must have a remedy no doubt where the medical man is negligent, and the courts should be open to all who have a just claim to prefer, but there must be some defect in our legal machinery to make the comparatively small and poor class of medical men run such risks for the good of the public. We have, perhaps, the most expensive legal system in the world, and it is one which lays all persons who are worth attacking open to the attack of anyone, be his claim just or unjust. And if the claim should be unjust the unfortunate defendants have no remedy. The pecuniary loss to the successful defendants in the case of SOPER *v.* GIBSON and YOUNG will be at least £100, even if the plaintiff is able to pay that proportion of the expenses now due from him in accordance with the verdict. It is a significant fact in this case that the solicitor who represented the plaintiff is the son of the plaintiff's employer; this the wife of the employer admitted when in the witness-box.

IT will be remembered that some few weeks ago considerable sensation was caused by the alleged abduction o

Madame DE MARTEL, widely known under her pen-name of "GYP." The story, as told with circumstantial detail by Madame DE MARTEL, went the round of the press of Europe, meeting everywhere with scant credence. And this was not, and is not, surprising, for undoubtedly it bore upon its face a striking resemblance to the episodes with which popular French romances are besprent, so that many who read the narrative experienced a feeling that what had occurred to the lady was too much like a chapter from one of M. XAVIER DE MONTÉPIN'S interminable and impossible novels to be an episode in real life. In particular medical men were unbelieving, for the invention of such stories by those posing as victims of assaults is a form of hysteria familiar to all of us. Consequently Madame DE MARTEL, though she was able to adduce corroborative testimony to parts of her story, and though her written work displays her as a woman of particular sanity, was very generally condemned as the victim of hallucination or of mad desire for notoriety. Possibly this condemnation was hasty. For M. KARL, the ingenious painter who hoaxed M. Q. DE BEAUREPAIRE so egregiously during the DREYFUS trial, has written to the *Matin* to say that he and three of his friends abducted "GYP" in much the way that she had described to a sceptical public. It appears from M. KARL'S confession that there were concerned in the assault on Madame DE MARTEL a gang of confederates and a complacent *cocher*, and that the drive to the distant suburb, the confinement in the deserted villa, and the escape from the windows of the second story were facts and not the imaginings of a mentally unstable person. If M. KARL'S account is true the reason why Madame DE MARTEL'S adventure looked too like the fictional heroine's misfortune to be credible becomes clear. M. KARL, in describing his method of kidnapping "GYP" has fallen back upon just those literary authorities from whom his victim was suspected of having plagiarised, and while universal opinion was right in refusing to believe the abduction to be a serious outrage it was wrong in attributing imposture to Madame DE MARTEL. If the communication to the *Matin* is untrue—a hypothesis with something to recommend it—the "joyous" KARL, as our contemporary calls him, must himself be in a curious condition of mental balance.

Practical joking is obsolete in this country, and no one of sense, especially no medical man, regrets the manners and sentiments of the time when it was held in consideration as a form of humour. Indeed, the disrepute into which practical joking has fallen may be pointed to without exaggeration as one of the most certain proofs—if proof be needed—that the race has attained to a higher plane of civilisation during the nineteenth century. A hundred years ago the practical joke flourished in England side by side with an elaborate social demeanour, the absence of which we are often called upon to deplore in the present less ceremonious days. But the appreciation bestowed by our grandfathers and their fathers upon practical jokes, however cruel, however dangerous to life and limb, and against whomsoever directed, does much to nullify the fine effect produced by the elegance of their clothes, the loftiness of their sentiments, and the formality of their diction. The callousness which derives amusement from the pain of another is now a subject of reprobation, while the extreme danger to health of many forms of practical joking has been pointed out by the medical profession in terms which have ensured the discontinuance of many favourite tricks. And this is a sign of progress. It proves that we have outgrown the schoolboy desire to inflict misery upon our neighbours that we may enjoy their mortification. Here and there a practical joke may still be tolerated, but it is certain that unless the victim is a man, and a man who has merited rough reproof, the sympathies of the spectators, even in the hilarious environment of a country house-party, will be with the victim. Those who laugh will laugh because they feel that the man who makes an unappreciated joke is in a more melancholy plight than the man against whom the joke is levelled. The position long enjoyed by THEODORE HOOK will not be filled in the twentieth century. HOOK was, as everyone knows, a greater and more honest man than his reputation, but the things that he did two generations ago only, while he was occupying a distinguished place in society and letters, would nowadays ensure his being expelled from his clubs. We have, in fact, put away this childish thing—practical joking, and that we have done so is more significant than a little. It is constantly said that modern life has lost all delicate aroma, the hurry and stress of competition leaving men no leisure to attend to niceties of behaviour. But, as in many an oft-repeated statement, the little piece of truth is outweighed by the general incorrectness. If there is less politeness on the surface now than in Georgian days there is infinitely more true courtesy. The desire to please is as great while the resolve not to give pain is far greater. In the days when practical joking was a favourite form of humour no one was exempt from the ferocity of the fun-maker. A glance at the literature, especially at the novels, of 50 and 60 years ago reveals that to be old, to be ugly, or to be a spinster, were all considered a sufficient reason for ridicule and even for personal assault. Coarse personalities reflected little discredit on the utterers, for a majority could always be found to join in a laugh at the butt. This spirit of cruelty has been largely eliminated in recent days, and as a consequence our estimate of what constitutes good breeding has changed for the better in a remarkable degree, which is the more a subject for congratulation in that it is the habit of the unthinking sweepingly to condemn modern English manners, which are found to be abrupt and only suited to a utilitarian folk. Possibly, but those who speak so forget that an exquisite appreciation of beauty, a gift of mellifluous phrase-making, and a courtesy of manner that is wearisome in its elaboration can exist in the savage breast. For what is the Chinese judged by modern standards but a savage? His centuries of semi-civilisation have never taught him to moderate his cruelty. The subjugation of the childish instinct to give pain is the truest sign of progression in a people. The possession of the fruits of learning and science, so generally acclaimed as proving attainment to a high level of living, is not so true a sign.

France has always, in theory at any rate, been the most finely civilised and gallant of nations. Many things have combined of late to render this view difficult to hold; for

example, the treatment by Frenchmen in certain of their newspapers of our venerable QUEEN and their own conscientious President. But those who have social relations with them will always be found to say that French politicians, whatever views they represent, are never representative of the people, and that French writers, and especially French journalists, appear to take pains to traduce their country. In these circumstances it will be interesting to see what attitude France takes towards M. KARL, supposing that M. KARL'S words are true. When M. KARL befooled M. DE BEAUREPAIRE he shook the world with laughter. The supporters and the adversaries of DREYFUS alike saw the ridiculousness of the position occupied by the ex-judge, and M. KARL leapt into fame. It is possible that the humorist took more credit to himself than he should have done, and that his second attempt has been based upon faulty comprehension of the conditions under which his previous exploit was performed. His opportunity with regard to M. DE BEAUREPAIRE was most fortunate, for that person had laid himself specially open to the punishment that he received, proving himself credulous and ignorant in the precise directions in which he was posing as shrewd and well-informed. No such conditions exist in the case of Madame DE MARTEL, and while it is doubtful whether France will laugh again, for the rest of the world the joke will fall flat. "GYP," like M. DE BEAUREPAIRE, brought trouble upon herself. She, like him, is a vigorous political partisan—"the Eurydice of the Nationalists" M. KARL terms her—and her attitude towards the Jews is as uncompromising as was M. DE BEAUREPAIRE'S towards DREYFUS. But having said this, all that can be urged in extenuation of M. KARL'S cruelty has been said. We find it much too little and we trust that Frenchmen, regardless of politics, of the DREYFUS question, and of the anti-Semitic movement alike, will find it the same. If M. KARL has invented the story of the abduction he has been willing to exhibit himself as a complete anachronism and not a funny one. If he has done what he says that he has done, he should be severely punished. For practical joking is a danger and a nuisance to society that should not be tolerated.

DR. DANFORD THOMAS, coroner for Central London and Middlesex, has drawn up a series of questions relative to the cause of death in cases in which a patient has died presumably owing to an anæsthetic. In England inquests are always held in the case of such fatalities, while in Scotland the law does not deem a special inquiry necessary if the medical man in charge of the case can give a satisfactory statement that the death was not due to gross carelessness or unprofessional conduct. The questions which Dr. DANFORD THOMAS has formulated deal with the choice of the anæsthetic, the place in which it was given, and all the circumstances attending the administration, such as the temperature of the room, the condition of the patient, and the nature and duration of the anæsthetic. They further request the medical man who gave the anæsthetic to state in how many cases he has given anæsthetics, how much air was allowed to mix with the narcotic vapour, the quantity of the drug used, and by what method it was given. The phenomena associated with the induction and continuance of anæsthesia, and attending the death of the patient, are also inquired into, as well as the general state of the patient with regard to the heart, lungs, kidneys, and other organs before the operation. The questions are extremely useful as a guide for the scientific inquiry into such sad occurrences as deaths under anæsthetics, but whether it is at all possible, or indeed desirable, to attempt in a coroner's court to enter so fully into the details of purely medical questions we venture to express a doubt. It is assuredly the function of the court to ascertain whether an individual died from, we will say, an overdose of chloroform through inexpertness or malpraxis of the administrator, but it seems to us that this end may be obtained without placing before the jury purely medical facts, which are not always within their purview, or, in some instances, within that of the coroner himself. The public attending such courts as well as the jury are not, as a rule, skilled in questions of anæsthetics, and might certainly receive false impressions if the technical medical statements contained in the report were presented in detail as evidence in the case. Even experts reading answers to Dr. DANFORD THOMAS'S queries might arrive at very diverse decisions. While one might condemn the method which his neighbour extolled, many might find a cause of death quite other than that which the administrator believed to be the true one. It is at least an ordeal for any medical man to appear in the coroner's court, having first suffered the mental shock incident to losing a patient under an anæsthetic, when he has done his best according to his lights for that patient. If to this be added a searching inquiry into the scientific questions involved, with possibly a severe heckling from jurymen whose want of technical knowledge is often apt to induce misunderstanding of scientific facts and to confuse the issues, the medical witness will hardly welcome the innovation suggested.

We may not unreasonably expect that Dr. DANFORD THOMAS will regard such reports as "private and confidential" *communiqués*, and that the evidence thus collected will result in the ascertaining of facts and details which will be of scientific interest and benefit to those employed in the administration of anæsthetics. Provided that such inquiries are conducted by medical coroners and the statements made by the medical witness are given purely for the guidance of the coroner and not for that of the jury, we think that Dr. DANFORD THOMAS'S schedule of questions is to be welcomed. But unfortunately all coroners are not medical and we cannot quite see of what use the questions, which are of a highly technical medical nature, would be in the hands of legal coroners. Certainly the suggestion now under consideration appears to us to add one more to the many reasons why in all cases coroners' inquiries should be conducted by medical men and not by lawyers.

GIFT TO BLYTH.—Sir Matthew White Ridley, the Home Secretary, who is lord of the manor, has given land of some extent to the Blyth District Council for a park for the use of the inhabitants of the seaport.

Annotations.

"Ne quid nimis."

THE METROPOLITAN HOSPITAL SUNDAY FUND.

WE publish in another column a letter from the Lord Mayor urging on the public of London in terms of admirable directness the absolute necessity of contributing this year to the utmost of their power to the Metropolitan Hospital Sunday Fund. His lordship evidently feels that there is reason for apprehension that the very heavy calls which have been made during the past nine months of war and suffering upon the public purse may influence in an unfortunate manner the subscriptions to the Fund. In our Special Suppement in behalf of the Fund issued last week we spoke of the position in much the same terms. We admitted that the demands upon the benevolent had been so very heavy that the Fund might this year find itself in difficulties, and to the best of our power we urged upon the public the true view—viz., that a year of national suffering is a year when this Fund requires more than ever all the pecuniary assistance that the public can afford. The Lord Mayor boldly asks the public to send him £100,000, that is to say rather more than double the average annual total of the Fund. It will be an event of almost national importance if the sum he asks for is obtained. The Fund has started splendidly. Mr. George Herring, whose great generosity to the Fund we have chronicled on previous occasions, has given towards this ideal total of £100,000 no less than £10,000, and has also promised to give £10,000 more if the sum of £90,000 is raised. In the name of the suffering poor of London we thank Mr. Herring for his splendid munificence and we trust that the necessary subscribers will come forward to deplete his open purse of the second donation. We beg our readers to remember that next Sunday is Hospital Sunday, and we hope that they will impress the fact upon all whom they can influence.

DOWLING *v.* DODS.

IN the Queen's Bench Division, before Mr. Justice Darling and a common jury, Miss Agnes Dowling, a certificated nurse, sued Mr. Louis Ferdinand Dods, L.S.A., a medical practitioner residing in Marylebone, to recover damages for libel. The alleged libel consisted in a letter which the defendant had published and written to the relieving officer of the Paddington district in which he certified that to the best of his knowledge and belief the plaintiff was of unsound mind. The letter also stated that the plaintiff had passed an examination at the Apothecaries' Hall for certification as a dispenser, and that in her present frame of mind this constituted a danger to the community. He had interviewed sundry people who agreed as to her insanity and were afraid of her. The plaintiff gave evidence in support of her case and was cross-examined by Mr. Hammond Chambers. She said that she had been an inmate of the House of the Holy Cross in Ladbroke-square and admitted that she had written several letters to the nurses. To Sister St. Clair, the assistant matron, she had written, "When I was on night duty and sleeping at your home you kept me awake often, and made me write letters to you at Fulham." That, she said, was by telepathy. She also said, "You tried to take my soul from me with your diabolical practices. ..... You took possession of my mind, you could read most of my thoughts, you threw me down in the streets one day because you did not approve of them." This she accounted for by "thought body" phenomena. In reply to the judge the plaintiff admitted that when she was in Ireland she distinctly heard Dr. Groves's voice. He was at the time in the Isle of Wight. Mr. Dods gave evidence as to seeing the plaintiff with Mr. Farrar, a tutor whose lectures she attended at Westbourne Park-road. He had seen plaintiff in Mr. Farrar's house waving her arms about and talking to herself. He wrote the letter in the plaintiff's interest. Mr. Farrar gave evidence of eccentric behaviour on the part of the plaintiff, and Miss Matilda Ashby, matron of the Holy Cross Society, a Roman Catholic institution for training nurses, said that the behaviour of the plaintiff while in the home was very strange. Mr. Justice Darling, in the course of his summing-up, read passages from the plaintiff's letters to Miss Ashby which, in his opinion, justified the defendant's statement that persons went in terror of their lives on account of the plaintiff. He held that the letter was privileged, but left the following questions to the jury:—1. Did the defendant write to the relieving officer without malice and *bonâ fide* believing that the statements were true. 2. Were the statements true? 3. Did the defendant act in good faith and with reasonable care in the manner in which he brought the matter before the relieving officer? The jury answered the first and third questions in the negative and assessed the damages at £100. With regard to the second question, the jury found that the defendant had not spoken truly in stating that the plaintiff was of unsound mind, that it was not true that the plaintiff had sent threatening letters, that it was not true that she would be a source of danger as a dispenser. It was true, however, that she had hallucinations. Judgment was therefore entered for the plaintiff. To our minds the finding of the jury is remarkable. We can see no evidence to show that Mr. Dods did not act in good faith, and plaintiff was admitted by the jury to have hallucinations. A dispenser who has hallucinations is, we should say, by no means unlikely to make disastrous mistakes. Suppose, for instance, that a prescription recommended salicylate of soda and the dispenser heard a voice from the Isle of Wight recommending the substitution of arsenic? It must be remembered, too, that Miss Dowling could not have been committed to a lunatic asylum on the strength of Mr. Dods's letter. That letter was only the commencement of a possible inquiry into the plaintiff's state of mind.

THE ALDERSHOT FIELD DAY.

AFTER the expressions of regret that have been made regarding the recent catastrophe at Aldershot and the desire which evidently exists to lose no opportunity of preventing any similar disaster in the future we might be presumed to be able to rest content. But we regret to say that we cannot regard the result of what had previously taken place in the House of Commons and the statement of the Under-Secretary for War as to its causes as altogether satisfactory. Apart from the loss of life and the suffering that were entailed, such occurrences cannot tend to popularise the army, which is what the Government and everybody else are desirous should be done at the present time. While we quite admit that the going astray of carts containing refreshments was a very unfortunate accident on the occasion in question and that the sudden accession of an exceptionally hot and close day could not have been foreseen, we nevertheless consider that under such circumstances it would have been prudent either to postpone altogether or to curtail the time of the intended military operations. This is not, however, the question which concerns us now. What the public has a right to expect is that the military authorities, with all the experience which they have had of field days, military manœuvres, and marches in and around Aldershot, should be able to show that all practicable precautions are taken against occurrences of this

kind. It is no doubt not advisable, even were it practicable, to depart from a system of decentralisation by taking out of the hands of the local military authorities the duty and responsibility of making adequate arrangements on occasions of this sort. We cannot see, however, how these arrangements can be considered adequate so long as soldiers about to take part in a long and trying field day are not provided before starting with a more substantial breakfast than they seem to get at present, together with means of obtaining light refreshment and an abundance of fluid *en route* and during halts. We know, as a matter of fact, that sportsmen and civilians take care to secure a good breakfast before commencing any unwonted exertion, and if the existing regulations do not admit of this being done on field days in the case of the soldier the War Office should issue the necessary authority and incur the cost of having it done. It goes without saying, too, that the men should be protected from the sun and the heat by suitable clothing and head-dress and by marching in as open order as possible. The so-called forage or field service cap is quite unsuitable for such occasions; either helmets should be worn or, what would probably be preferable, the slouched form of head-dress used by the colonial troops should be adopted by our infantry soldiers. But it is of little use merely to protect the head against the direct rays of the sun so long as the danger from heat exhaustion arising from insufficient nourishment and fatigue be not also guarded against. It is often a matter of emulation with corps to "force the pace" in marching back to camp after a field day and it was on the return march that the soldiers, overcome with heat and fatigue, fell out in such numbers, and it is at such a time, therefore, that extra care should be taken.

THE ROYAL SOCIETY (SECOND) ANNUAL CONVERSAZIONE.

THE exhibition held by the Royal Society on June 20th, although containing very little of an entirely novel character, yet fully maintained the high standard it has reached in recent years. It frequently happens that the second or June conversazione, generally known as "ladies' night," is more or less a repetition of the one given in May. This year, however, we are glad to find that this is by no means the case, many fresh subjects of interest being brought forward. An able demonstration of an apparatus for the production of short electric waves and the study of electro-optic phenomena was given by Dr. J. A. Fleming, F.R.S. A beam of electric radiation was produced by a radiator, the wave length being about eight inches. External radiation is prevented by enclosing the instrument in a zinc box. The receiver is of the Branly type and is connected with a relay and an electric bell to indicate the impact of electric waves. Dr. Fleming showed that the latter could penetrate ordinary insulating screens but were at once stopped by those made of metal. Damp objects, such as a wet duster, a moist brick, or the human body, were quite impervious. The refraction of these waves was also cleverly shown by turning the radiator out of the horizontal plane when the receiver bell gave no indication until a prism of paraffin wax or a grating of parallel wire held at an angle diverted the rays into the aperture of the receiver. The spectra of the inert gases of the atmosphere were exhibited by Professor W. Ramsay, F.R.S., and Dr. M. W. Travers, who have now succeeded in thoroughly separating no less than five constituents from atmospheric nitrogen—viz., helium, neon, argon, krypton, and xenon, spectra of these five gases in a pure state being on view. It is interesting to notice that krypton with an atomic weight of about 80·54 comes close to bromine in the Periodic Law, whilst xenon again, with an atomic weight of 128, is close to iodine. An ingenious apparatus for the preparation of these gases in the pure state was also shown. It consists mainly of mercury levelling tubes, by means of which atmospheric air is driven into a tube, cooled by liquid air, and thereby compelled to condense. Diminution of pressure then causes the highest boiling liquid to vaporise away from the others, thereby practically bringing about fractional distillation of the gases present. The photographic observations of the solar eclipse of May 28th formed the interesting exhibit of the Joint Eclipse Committee of the Royal and Astronomical Societies. Many positives and negatives of the various stages of the eclipse were on view and naturally many of the corona. Ordinary and chromosphere spectra of the latter were also shown, and among other attractive items in this collection were some striking paintings by Mr. Wyllie, the well-known marine artist, of incidents which he witnessed whilst accompanying the official expedition. Dr. William J. S. Lockyer showed some clever photographs of bright and dark lightning flashes, the effects being purely photographic, probably caused by several sparks of varying intensity taking place at the same time. The poisonous lotus of Egypt (*Lotus Arabicus*) was shown by Professor Wyndham Dunstan, F.R.S. This very curious plant possesses the property of being extremely poisonous to animals in its living condition from the formation of prussic acid due to the action of water on a glucoside it contains, an enzyme present converting the latter into this poison and a yellow colouring matter, *loto flavin*. When, however, the plant is cut down and dried it becomes a most useful fodder and possesses an odour closely resembling fresh hay. Dr. W. J. Russell, F.R.S., showed some pictures on copper developed by iodine after contact with printer's ink and also after exposure to hydrogen peroxide. Some ancient cameos and gems dating back to the second or first century B.C. were exhibited by Sir John Evans, K.C.B., F.R.S., and some of the Roman remains from Silchester by Mr. W. Gowland. The latter included some fragments of the hearths of two of the old cupellation furnaces saturated with lead and copper oxide during the extraction of silver from argentiferous copper. Some very good experiments were performed by Professor Hele-Shaw, F.R.S., and Mr. Hay on stream line motion analogous to lines of magnetic induction. They exhibited a specially constructed glass plate by means of which a large number of results may be obtained with very little trouble suitable for both educational and research work. Last, but not least, Professor E. Ray Lankester, F.R.S., showed two ingenious models of mosquitoes enlarged 28 times linear and some models of human blood-corpuscles infested with the malaria parasite.

UNFOUNDED CHARGES AGAINST THE CARDIFF INFIRMARY.

THE working men of Cardiff and the colliers of the surrounding districts subscribe about £1000 per annum in support of the Cardiff Infirmary, not by any means a large amount when compared with the sums raised on Hospital Saturday in other large towns, Birmingham for instance. But if the Cardiff workmen are grudging in pecuniary support they are only too ready to bring against the staff of the institution charges which are of the most trivial nature and which will not bear even the most superficial examination. The latest instance occurred last week when at a meeting of the working-men governors it was stated that a collier who had met with an accident was sent by the colliery surgeon to the infirmary and that although he had a subscriber's ticket he was sent home without having his injury attended to. Such is the statement which appeared in the Cardiff daily papers of June 12th. The actual facts are these. A collier in one of the Rhondda valley collieries badly crushed three of his

fingers and was attended immediately by Mr. Edwards, the colliery surgeon, who was of opinion that with proper treatment the whole hand would be saved. At the end of two days the man suggested that he should see one of the Cardiff Infirmary surgeons and Mr. Edwards readily acquiesced. Upon presenting himself at the out-patients' room of the infirmary Dr. P. Rhys Griffiths made a careful examination of the injured hand and came to the same conclusion as the colliery surgeon, that there was no necessity to amputate any of the fingers, and after having the hand dressed he wrote to Mr. Edwards giving expression to his views as to the mode of treatment to be followed. It is thus evident that instead of receiving scant courtesy, as the working-man governor would have his colleagues believe, this particular patient received exceptionally good treatment at the hands of the infirmary surgeon. It is a great pity that such charges as these should not be investigated before finding their way into the daily papers and not after. Those who bring them must surely see that even the interval of the couple of days which must elapse before explanation is possible may be long enough to do a considerable injury to the institution whose interests we are convinced they have really at heart.

MARRIAGES BETWEEN PERSONS OF THE SAME SEX.

THE determination of the sex of a new-born child with malformed genital organs must often be a matter of considerable difficulty. With the advance of years and the advent of puberty the changes which take place in the body and the development of secondary sexual characters usually enable a correct diagnosis to be made. It would seem hardly credible that individuals could grow up and even enter the marriage state without their exact sex ever having been determined. In two articles of great interest in the *Revue de Gynécologie et de Chirurgie Abdominale*, March–April, 1899, and January–February, 1900, Dr. François Neugebauer has collected notes of no less than 53 cases of marriage between persons of the same sex. He has also collected from the literature 11 cases in which marriage engagements were broken off on the discovery of an error having been made in the sex of one or other of the parties, and 15 cases of "women" living a life of prostitution who were in reality of the male sex. A careful examination by a competent observer will rarely fail to determine with certainty the sex of a new-born child, but in many cases the matter is left to the judgment of the attendant nurse or midwife, who has not a sufficient knowledge of the various kinds of malformation of the genital organs to enable her to come to a correct conclusion. The unfortunate consequences that may result from an error are illustrated by Dr. Neugebauer's cases and by the fact that two unhappy victims of such a mistake were driven to commit suicide. In the 53 cases recorded, in 49 a man had been married as a woman, in three cases a woman had been married as a man, while in one the person was said to be an hermaphrodite. The majority of the cases of the men appear to have been very evident cases of peno-scrotal hypospadias. Some of these cases, however, even when examined by trained observers, cannot be decided upon with absolute certainty unless a microscopical examination of the supposed ovaries or testes is possible. The legal relations of the correct determination of the sex of a new-born child may be of the greatest possible importance. The question of the right of succession or inheritance to landed estate or to an estate limited by entailment may depend upon a correct appreciation of the preponderance of one or the other sex in the case of an hermaphrodite. If the subject of such a malformation die a short time after birth the rights of other people may rest to a large extent upon the decision of the medical attendant in the matter of the exact sex. In such cases no conclusion should be come to without the most complete post-mortem examination and if necessary a microscopical examination of the sexua glands. The law in France with regard to the nullity of marriage between two persons of the same sex differs from that in this country. If the person married is a malformed woman incapable of sexual intercourse then according to the French law no ground exists for declaring the marriage void. Such a condition is, however, recognised by English law as a sufficient cause for annulling the contract. If, on the other hand, the person is a malformed man there can have been no legal marriage and it is of necessity null and void. If the case is one of an hermaphrodite then nullity of marriage must exist since whatever the sex of the other contracting party there must be identity of sex between the two persons. In view of the grave results that may ensue cases of doubtful sex should be investigated with the greatest care, and in all cases where any doubt remains the child should be brought up and educated as a male.

THE COLONIAL SURGEONS IN ASHANTI.

THE dangers which are at present threatening our countrymen in the West Coast of Africa have a special interest for the medical profession from the fact that of the 26 Europeans whom the revolted Ashantis are believed to have surrounded in Coomassie no fewer than six are in the Colonial Medical Service. Under the most favourable conditions these gentlemen have very arduous and responsible positions, and the climate in which they live is proverbially one of the most fatal in the world for white men. At present they are in a most critical position, shut up in a native town far from the sea and with no immediate prospect of being relieved. These victims to duty, with whom we have to express the utmost sympathy, are Mr. Patrick Joseph Garland, senior assistant colonial surgeon, Gold Coast, Mr. Edward Herbert Tweedy, Mr. Albert John Chalmers, M.D. Vict., Mr. William Medlycott Graham, M.B. Dub., and Mr. J. B. Hay, M.B. Edin., assistant colonial surgeons, Gold Coast, the sixth being Mr. W. F. Macfarlane, assistant colonial surgeon, Lagos. All will unite in hoping that communication with Coomassie may be soon restored and the Europeans enabled to make their way to the sea-coast.

THE RATING OF SCIENTIFIC INSTITUTIONS.

THE Jenner Institute of Preventive Medicine has recently attempted to obtain exemption from the payment of rates and has failed to do so on its case coming before a Divisional Court. The ground of its claim to be excused was that the Jenner Institute came under the Act of Parliament passed in 1843 which exempts "any society instituted for purposes of science, literature, or the fine arts exclusively," provided that such society fulfils certain other conditions. It was not contested that the Jenner Institute did not fulfil these or that it was not instituted for purposes of science, but its difficulty arose from the application of the word "exclusively." It is, of course, well known to our readers that the Jenner Institute is not only responsible for much scientific investigation and research but also that it manufactures and sells antitoxin, mallein, tuberculin, and similar preparations for the benefit of members of the medical profession who are glad to be able to obtain them from such a source. It was not suggested to the Divisional Court that it carries on a profitable business in this respect; indeed, it was admitted that some of the preparations named were sold at a loss to the institute. The judges, however, held that giving full weight to the word "exclusively" in the Act under consideration they were bound to consider the appellants liable, Mr. Justice Channell

saying that "one of the objects of the appellants was no doubt the promotion of science, but one and probably the main object was to dispense to the public the benefits of science." We do not quite follow the distinction thus drawn which we cite from the *Times* report of the case, and we should have thought that "the dispensing of the benefits of science" to the public should hardly, according to the spirit of the Act, impose a liability from which a society not so dispensing them would be exempt, but we do not wish to re-argue a case which no doubt will shortly be re-argued to the full in the two courts which still remain open to it. We would rather protest against scientific societies having either to submit to taxation or to expend their revenues in claiming the protection of an Act of Parliament passed more than half a century ago and so vague in its terms that even now the interpretation of its provisoes is wholly uncertain, while such institutions as general hospitals might well have been included in its scope had they not at the time of its passing and for many years afterwards been universally deemed to be under no obligation to pay rates. In justification of what we have said as to the uncertainty and consequent cost of such an appeal as the Jenner Institute seems to have undertaken we need only point to the history of two more or less recent appeals under the same section which were cited in the course of argument in the Divisional Court and which we select at random. In the one case the Institution of Civil Engineers was the appellant. The Divisional Court decided against it. On its appealing to the Court of Appeal the decision of that tribunal was in its favour by a majority, one out of the three Lords of Appeal dissenting from the other two. In the House of Lords the Institution was again successful, but again one judge out of three—the Lord Chancellor, to wit—was against it and it succeeded by a bare majority only. In the other case the Art Union of London was the appellant. The Divisional Court decided against it; the Court of Appeal was in its favour, being, however, again divided in the proportion of two judges against one; and the House of Lords eventually reversed the decision of the Court of Appeal and held the Art Union liable. It is possible that the law on the subject of exemption from rates may have been rendered clearer by these two decisions and may be clearer still by the time the Jenner Institute has secured another from the House of Lords, but it seems time to amend, or to replace with a modern one, an old statute passed two generations ago which is still fraught with expensive litigation for the very institutions whose revenues it was passed to economise and which omits from its purview others equally deserving protection.

IRISH UNIVERSITY EDUCATION.

ALL Irishmen are naturally fond of discussion, and at the present time university education provides them with a most congenial subject, so that the question is constantly arising and the number of views put forward as solutions of the matter illustrates the proverb, "*Tot homines quot sententiæ.*" Here is the latest. At the yearly meeting of the Assembly of the Presbyterian Church in Ireland, held in Dublin on June 8th, the convener of the Committee on Higher Education strongly commended as an equitable solution of the university question "the nationalisation of Trinity College," by which was meant that the theological degrees, as well as the degrees in arts and other faculties (medicine, law, &c.), should become the property and privilege of the whole nation. According to this utopian scheme the Ulster Faculty—the six Presbyterian theological professors in Belfast and the three in Derry—should undertake the conducting of classes in Trinity College, Dublin, by availing themselves of the Trinity term that lies outside their own session. What the unfortunate professors in arts, law, and medicine of Queen's College, Belfast, or the arts professors of Derry would do under this scheme is apparently not worth considering. It need hardly be said that such a settlement—as the interesting debate showed, when it was broached—would be unworkable. In the first place, no statesman of any party would attempt to interfere with Trinity College, nor does any true Irishman wish to destroy the prestige and glory of a university the traditions of which go back to the days of Queen Elizabeth; secondly, it would be absurd to expect other educational bodies to join Trinity College unless on terms of absolute equality on the governing senate, as well as in other matters—a condition which Trinity College would never yield; and, finally, such a proposal as the nationalisation of Trinity College would in no way satisfy the Roman Catholic Church in Ireland, and the problem, as far as it is concerned, would be as acute as ever. The proposal to nationalise Trinity College is, therefore, as useless as it is impracticable.

THE LATE MRS. GLADSTONE.

ON June 14th Catherine Gladstone, the wife of perhaps the most notable statesman of the expiring century, passed from sleep into death. She was in her eighty-ninth year and no transit from this world to the next could have been more peaceful. Nearly all the members of her family were present—a family as devoted to their mother as she to them and to any one of whom the exquisite lines of Pope might apply—

> "Me, let the tender office long engage,
> To rock the cradle of reposing age,
> With lenient arts extend a mother's breath,
> Make languor smile and smooth the bed of death,
> Explore the thought, explain the asking eye,
> And keep awhile one parent from the sky."

To the deceased lady the medical profession owes a great debt in that she was the pioneer of the free convalescent home movement. It grew out of the distress caused by the cholera epidemic of 1866 which forced upon her attention the necessity for such institutions. She appealed to the public and generous donations were sent in including one of £1000 from the Queen. The first home was opened at Snaresbrook, but it was transferred in 1869 to Woodford. From the beginning she set her face against granting to subscribers any privileges in the way of "letters" or nomination of patients, and this opinion was endorsed at a great meeting held at the Mansion House in 1876, where Mr. Gladstone spoke.[1] This of course is the way in which any charity should be worked, but we fear that such a method needs the personal magnetism of a Gladstone to make it generally feasible. No better memorial could be raised to the memory of her who has gone than for one of the large London hospitals which has not already done so to do away with subscribers' letters.

RESULTS OF THE TREATMENT OF GRAVES'S DISEASE BY REMOVAL OF THE THYROID GLAND.

G. REMBACH contributes to the *Deutsche Medicinische Wochenschrift* of April 26th, 1900, a concise and very instructive review of the cases treated by removal of the thyroid gland in exophthalmic goitre. Nearly a decade has passed since Mikulicz of Buda-Pesth operated on his first case of Graves's (Basedow's) disease, and the final results are very gratifying to record. All the clinical symptoms of a disagreeable and distressing nature (palpitations, attacks of giddiness and of confusion, flushings and feelings of heat), have been entirely, or almost entirely, removed by the operation and the patients have been able to pursue their usual occupations and to enjoy their lives which before were wearisome and wretched. A

[1] THE LANCET, April 1st, 1876, p. 507.

review is given of 18 cases which had thus been operated on with beneficial results. It may be mentioned that resection of the thyroid gland was successfully performed in 13 cases and enucleation in three cases. Bilateral resection was found necessary in six cases, and in four of these it was completed at one sitting. The arteries supplying the thyroid gland were ligatured in five cases. Microscopic examinations were made of the excised glands, but the changes found were slight and variable. No constant pathological basis could be discovered, so that, apart from the view generally entertained that the gland is in a state of hyperplasia and over-activity in this disease, no specific statement on the pathology of the disease could be put forward.

THE QUESTION OF HORSE AMBULANCES.

OUR recent reference to horse ambulances has stimulated afresh interest in this important question, and among the correspondence relating to the matter which has reached us is a note from the Hon. F. Dudley Leigh calling our attention to an article from his pen in the *Nineteenth Century* for October, 1896. The author succinctly sketches the work that has been done in this direction in other countries; his descriptions of the celerity with which the American ambulances start out, picking up a surgeon on the way, being as thrilling as an account of the almost instantaneous receipt of a call and the turn-out of the New York Fire Brigade. Mr. Leigh concludes his paper with suggestions that various public bodies might interest themselves in the question, pointing out that our hospitals are too overburdened already in the matter of finance to take up the matter themselves. It is certainly to be regretted that, in an age when every possible effort is apparently being made to alleviate suffering, London should be behindhand in providing that rapid means of transport in the case of accidents which is provided not only in America and on the continent but also, we are happy to know, in Belfast, in Bolton, in Oldham, and which will soon, we trust, be provided in Manchester. Oxford, too, as will be seen from a letter in another part of THE LANCET, has done something towards providing transport of the kind in question. Surely if the matter were taken in hand by some responsible body there would be no lack of funds for the wiping out of what is now a blot upon our city.

THE PLUMBERS' REGISTRATION BILL.

IT is satisfactory to notice that our contemporary the *Daily Express* is making an effort to arouse public interest with regard to the importance of sound plumbers' work. This is the more opportune as that much-neglected measure, the Plumbers' Registration Bill, will shortly be again before the notice of Parliament. It may be that the lack of general interest exhibited towards this Bill by Members of the House is more apparent than real, but it would seem to exercise a heavy narcotic influence whenever it is introduced. Some measure of control over men operating as plumbers is surely needful; this is more particularly the case when, under the present conditions of the building trade, such work is undertaken by employers whose ostensible avocations by no means guarantee their ability to direct their workmen in the intricacies of their craft. Probably not half the workmen engaged in plumbing work are employed by master plumbers. Any man calling himself a builder, as well as ironmongers, gasfitters, stores, or universal providers are gradually wresting the trade from the master plumber. The employés suffer from this, the men having to a large extent to pick up a knowledge of their trade as best they can, the old system of apprenticeship rapidly becoming extinct with the decadence of the master plumber. The powers for evil that repose in the hands of these men have been frequently pointed out in the pages of THE LANCET. The disastrous effects that arise from their callousness or ignorance are constantly presenting themselves to our notice. The best men are all anxious for registration; it is only those who could well be spared from the trade who are inclined to reject it.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MR. J. A. BLOXAM, senior surgeon to Charing-cross Hospital, having decided to become a candidate for a seat on the Council of the Royal College of Surgeons of England, Mr. John H. Morgan has withdrawn his name from the list of candidates.

CAMBRIDGE SUMMER SCHOOL OF MEDICINE FOR QUALIFIED PRACTITIONERS.

WE have already given some details as to the Cambridge Summer School of Medicine which it was intended to hold from June 25th to June 30th. Demonstrations of the malarial and other blood parasites and of all the most recent work on cancer had been arranged for, while in addition to these subjects lectures were to have been given by experts in their several lines of work upon various other matters of medical and surgical interest. We regret, however, to have to announce that owing to the small number of acceptances it has been decided not to hold the meeting. The response with which the offer has met with this year is all the more disappointing after the enthusiasm and gratitude of the visitors at the last meeting five years ago and we learn that the offer will not be made again.

MEDICAL MEN AND HOSPITAL BOARDS.

FROM time to time we have to record differences of opinion between the board of management and the medical board of the same hospital. When, therefore, we find evidence of great cordiality between the two boards it affords us much gratification to chronicle the same. The board of management of the Wigan Infirmary at the first meeting of the new board appointed Mr. William Berry, the senior honorary surgeon and secretary of the medical board, to be chairman of the general board for the ensuing year. That a medical officer of an institution should have been appointed to such a high post as the chairmanship of the general board of that institution is not only a high compliment to the medical profession but also a tangible proof that the working of the Wigan Infirmary is conducted upon the most harmonious principles and therefore upon the system calculated to give the best results both for the patients and for the supporters by whose generosity the needful funds are found. Wigan has set an example worthy of general imitation, and we offer those concerned in this happy procedure our warmest congratulations.

EPSOM COLLEGE: THE WAKLEY PRIZE.

ON June 16th the Council of Epsom College, on the occasion of their annual visit, awarded the prize for "Elocution" to the Senior Prefect, Mr. Colin Giffard, whose renderings of a portion of "Lear" previously "set," and of an extract from "The Spectator," which he had not previously seen, were equally excellent. To the same student was also adjudicated the "Wakley Prize." This prize is the result of a collection made by the friends of the late Thomas Wakley. The amount collected was invested and the dividends provide the funds for the prize in perpetuation of the memory of the Founder of THE LANCET. The prize is awarded to "the best fellow all round" by the votes of the boys in Upper and Middle School; on the present occasion the majority of votes gained was, we understand, the largest on record, whilst the endorsement of the staff was unanimous. The fact that a boy holding the

responsible post of Senior Prefect should have succeeded in winning so completely the approbation of the staff and the affection and confidence of his fellow-students implies the possession of a combination of qualities which we trust will stand him equally in good stead in his future career. Founder's Day will be held on Saturday, July 28th.

THE PATHOLOGICAL SOCIETY OF LONDON.

A NEW departure in the form of an extra meeting held in the Pathological Laboratory of the New Museums at Cambridge will bring the present session of the Pathological Society to a close. By the kind invitation of Professor G. Sims Woodhead the meeting will take place at 4 P.M. on Saturday, June 30th, at Cambridge. A list of the communications will be published in our Diary on Friday next. Members will be able to obtain dinner in hall at Trinity Hall at 6.30 P.M., so as to enable them to catch the 8.40 P.M. train back to town.

THE President and Council of the Medical Graduates' College and Polyclinic are issuing invitations for a conversazione to be held at the College, 22, Chenies-street, W.C., on Wednesday, July 4th. The reception by the President will take place at 8 P.M. and an address—subject, "The Teaching of Practical Medicine"—will be delivered by Professor Osler, F.R.S., of Baltimore, at 9 P.M. All inquiries should be addressed to the medical superintendent of the College, 22, Chenies-street, W.C.

THE Society of Arts Albert Medal for the present year has, with the approval of H.R.H. the Prince of Wales, president of the society, been awarded to Mr. Henry Wilde, F.R.S., "for the discovery and practical demonstration of the indefinite increase of the magnetic and electric forces from quantities indefinitely small." This principle is the one on which the invention of the modern dynamo machine is based and is employed in all modern dynamos.

THE Caroline Institute of Stockholm has just admitted a lady for the first time to the degree of Doctor of Medicine. Miss Anna Stecksén produced a thesis on the Blastomycetes of Curtis partly from studies under Dr. Roux in the Paris Pasteur Institute, and partly from work carried on in the bacteriological laboratory of the Caroline Institute.

THE governors and medical staff of Guy's Hospital are sending out invitations for a garden party to be held on Wednesday, July 4th, at 3 P.M., on the occasion of the distribution of the medals and prizes to the students by the Earl of Pembroke. The new laboratories, wards, museums, and college will be open from 3 to 5.30 P.M.

MR. C. A. BYNOE, concerning the justice of whose conviction for forgery in 1892 grave doubts have arisen, has applied unsuccessfully to the High Court for a rule *nisi* for a *mandamus* to compel the General Medical Council to hear the application that his name, which had been erased from the Medical Register, might be restored.

IT is an open secret that grave differences have arisen between the board of management and the medical staff of the National Hospital for the Paralysed and Epileptic, Queen-square. The medical staff have now drawn up a statement of their views which has been sent to the Governors of the hospital.

WE regret to learn the death of Mr. Thomas Jones, F.R.C.S. Eng., Professor of Surgery in Owens College, Manchester, and surgeon to the Manchester Royal Infirmary. Mr. Jones was surgeon in charge of the Welsh Hospital at the seat of war and his death is announced from Springfontein.

A TELEGRAM from Sir C. Bruce, Governor of Mauritius, to Mr. Chamberlain, received at the Colonial Office on June 15th, states that no cases of bubonic plague have been reported for the week ending June 14th.

THE annual distribution of prizes to the students of Charing-cross Hospital will take place on Tuesday, June 26th, at 3.30 P.M. The prizes will be distributed by Mr. H. Beerbohm Tree.

A TELEGRAM has been received at the Colonial Office, dated June 18th, stating that 74 cases of bubonic plague occurred in Ceylon last week with 64 deaths.

SIR WILLIAM MACCORMAC will receive the degrees of M.D., M.Ch. honoris causâ in the University of Dublin on Thursday, June 28th.

ROYAL ARMY MEDICAL CORPS SOUTH AFRICA FUND.

PRINCESS CHRISTIAN, the President of the Royal Army Medical Corps South Africa Fund, presided on June 19th at a meeting of the general committee of the Fund, held, by permission of Lady Broadbent, at 84, Brook-street, W. Her Royal Highness, who was attended by Miss Loch, was received by Sir William and Lady Broadbent, Sir Dyce and Lady Duckworth, and Surgeon-General H. S. Muir, Deputy Director-General of the Army Medical Department. Amongst those present were Miss Maxwell Müller, R.C., Lady Dyce Duckworth, Mrs. Anderson, Mrs. Berkeley Hill, Mrs. Ramsden, Mrs. Howard Tooth, Mrs. Jameson, Miss Quain, Mrs. Walsham, Mrs. Butlin, Lady Brunton, Mrs. Percy Kidd, Major and Miss Wilson, Mrs. Charters Symonds, Colonel and Mrs. Frank Howard, Mrs. Muir, Mrs. Thomson, Mrs. Barlow, Lady Savory, Mrs. Moore, Mrs. Hale White, Lady Russell Reynolds, Mrs. Church, Mrs. Pye-Smith, Mrs. Bradford, Mrs. Liveing, Lady Clark, Lady Fayrer, and Mrs. Charlton.

Mrs. CHARTERS SYMONDS (the honorary treasurer) in submitting her report, said: Your Royal Highness, ladies, and gentlemen,—As there may be no other opportunity of informing the committee and subscribers as to the distribution of the Fund, it may be advisable to enter into a few particulars. The total amount received to date is £2266 8*s*. 4*d*., which may be considered a successful result of our appeal. Messrs. Holt and Company have received £277 10*s*. 9*d*., and to this firm we are indebted for acting as our bankers. The committee formed in Birmingham have sent £225, and have also written to say that a further collection will be made if required. £50 have been received from the Leeds committee and £38 12*s*. 6*d*. have been received from Scarborough, while the Blackburn committee have contributed £80. The subscriptions sent direct to the treasurer amount to £1029 6*s*.; of this sum it may be added that the bulk was collected by the ladies of the committee and by members of the medical profession; a large sum also was raised by the Royal Army Medical Corps, due to the efforts of active and retired officers and to the wives of several gentlemen at present serving in South Africa. £29 were received from the officers and men of the Royal Army Medical Corps at Malta. We have expended £1495 11*s*. to date, including about £300 on flannel shirts and over £220 on tobacco. We have sent £200 to the principal medical officers in India, who purchased and despatched blankets and puttees to the Indian dhoolie-bearers now serving with the forces in South Africa. Major W. G. A. Bedford, R.A.M.C., secretary to the principal medical officer at Cape Town, has acknowledged the receipt of £200 which he will spend at his discretion and of which he will render an account to us. With regard to the auditing of the accounts Surgeon-General Muir has kindly offered to undertake the duty in

conjunction with some other officer in his department. We have in hand at present a balance of £770 of which probably £120 will be required for rent, packing expenses, and purchases up to the end of July. If we set aside another £50 for pipes and tobacco there will still be left a balance of £600; and one of our objects in meeting here to-day is to consider the best means for utilising this sum for the benefit of the corps whose splendid work in South Africa has been a striking feature throughout the whole campaign. I will leave it to Surgeon-General Muir, to whose courtesy and ready help we owe so much, to suggest the best way of dealing with this amount.

On the motion of Sir DYCE DUCKWORTH the report was adopted.

Surgeon-General H. S. MUIR then read the report of the Executive Committee. He said: Your Royal Highness, ladies and gentlemen,—The circulars which you have received have given particulars of what has been done, but a short recapitulation perhaps is desirable. Mrs. Charlton has been working at Netley, Mrs. Allin at Aldershot, and Mrs. Wilson and Mrs. Exham at Devonport, and several ladies of rank in the provinces have given their assistance. In January a letter was prepared for publication, when Mrs. Charters Symonds wrote to the Director-General of the Army Medical Department offering her kind assistance. This led to the formation of a central committee of ladies in London, and on Feb. 5th a meeting by the kind courtesy of Lady Duckworth was held at 11, Grafton-street, to organise and commence work. Your Royal Highness then graciously consented to be the honorary President. An executive committee was then appointed and an office was opened at 100, Victoria-street, Miss Maxwell Müller kindly undertaking the office of honorary secretary and Mrs. Charters Symonds that of honorary treasurer. Parcels of comforts were sent to the principal medical officer of each division and to all general hospitals for distribution. The work expanded rapidly; numerous gifts in kind began to arrive and the accommodation at Victoria-street proved insufficient for our needs and necessitated our finding the new offices in George-street. This change, however, entailed the loss of the services of Miss Maxwell Müller, who had devoted much time and energy to the work. Mrs. Muir then became honorary secretary, but the secretarial work had become so extensive that it was absolutely necessary to appoint a paid secretary and the executive committee were fortunate in obtaining the services of Miss Bollast. Parcels were now sent to the men at the base depôts, the advanced depôts, on the lines of communication, and to the hospital trains and hospital ships. The army had increased in numbers and new divisions were formed which necessitated the despatch of comforts to new detachments of the corps, which now included Militia and Volunteer Medical Staff Corps. Steps were taken to provide the Indian hospital attendants and dhoolie-bearers with blankets and puttees which were sent direct from Bombay. It was also considered advisable to commence sending a second consignment to the various divisions and hospitals. Upwards of 9000 parcels have now been despatched. The parcel for each man, as a rule, was made up of a flannel shirt, two pairs of socks, two handkerchiefs, a woollen helmet or cap, a muffler, a cholera belt, a pipe and tobacco, a cake of soap, a packet of note-paper, and a pencil. Occasionally some of the following articles were added: Testaments, towels, mittens, chocolate, compressed soup, lime-juice tablets, slippers, cigarettes, buttons, playing-cards, and bootlaces. About 100,000 articles have been despatched, and as a very large number of these were gifts in kind the committee wish to acknowledge these with many thanks. They numbered as follows: 2500 shirts, 3500 cholera belts, 14,000 caps, 3600 bootlaces, 6000 mufflers, 11,000 handkerchiefs, 12,500 pairs of socks, and 1200 pencils. I beg to mention that we are indebted to your Royal Highness for many of these articles. Many articles more suitable to hospital patients than for our purposes were sent to us, probably through misapprehension, but we did our best to forward them to hospitals, so that the generous donors may feel satisfied that the articles were duly used and appreciated. These articles include pyjamas, cushions, nightingales, bed-jackets, eau-de-Cologne, games, and magazines. The kindness of the following ladies must be acknowledged:—Lady Dyce Duckworth, Lady Lauder Brunton, Lady Broadbent, Mrs. Berkeley Hill, Mrs. Barlow, Lady Bertram, Mrs. Pye-Smith, Mrs. F. Taylor, Mrs. Morriston Davies, Mrs. Jameson, Mrs. Macpherson, Mrs. Johnston, Miss Bostock, Miss Wilson, Mrs. Dawson Williams, Mrs. Squire, Mrs. Greer, Miss Verona Brooke, Mrs. Oliver Barnett, Mrs. Clutton, Mrs. Bourke, Mrs. Garrett, Mrs. Steele Perkins, Mrs. Frank Howard, Mrs. Bradford, and Mrs. Forsyth. The packing of the thousands of articles which we have dispatched devolved upon a sub-committee, the members of which arranged amongst themselves as to their attendance daily. The amount of physical energy required to make up 9000 individual parcels has, I need hardly say, been very considerable, and the efforts of these ladies are worthy of the highest praise. I may add that two of the ladies mentioned voluntarily attended every day, wet or fine, and in this connexion I cannot refrain from mentioning the names of Mrs. Meredith and Miss Bowker. Our thanks are also due to the provincial committees who have done good work. Leeds, Birmingham, Liverpool, Scarborough, Blackpool, and Edinburgh have sent gifts both in money and in kind. The meeting has heard from our honorary treasurer that a balance of over £700 remains available. Subscriptions still come in from day to day, but we can hardly expect, unless we make special and earnest appeals, that any large amounts will be received henceforward. Judging from the course of events I think we may, perhaps, conclude that no such appeal will be necessary. At the same time it might be somewhat premature at present, for the reasons I shall now adduce, to declare the Fund closed. From some of the consignees we have heard of the actual receipt of our packages, but not from all. Now, that does not necessarily mean that the packages are absolutely lost, for it was only by the last mail that we heard of the arrival at Estcourt of the bales addressed to No. 7 General Hospital. We know that the traffic on the South African railways has been so congested that thousands and tens of thousands of packages of all sorts have been accumulated at wharves, railway-stations, and storehouses, and from what we learn there has no doubt been a certain amount of stealing. But the Royal Army Medical Corps are no worse off than others in this respect, and we know that hospital stores have been delayed by the more urgent necessity that food-supplies for the fighting line should have precedence. The executive committee therefore propose, with your sanction, to be guided by the information we obtain by successive mails and to send out supplies to those detachments which have been up to now by force of circumstances deprived of them. They consider, however, that it will not be necessary to keep the offices open after the end of July and to obviate the necessity of calling another meeting they propose to publish a report—probably the final one—at a date shortly afterwards, when they will be prepared to make a suggestion as to the disposal of any surplus that may then exist.

Sir WILLIAM BROADBENT moved the adoption of the report, which was agreed to.

Major WILSON moved a vote of thanks to the ladies and others who had given assistance. He said he was receiving now very pathetic letters asking what had become of the Queen's chocolate, and he need hardly assure Her Royal Highness that that matter was being most carefully looked after. It could no longer be said that the Royal Army Medical Corps, who were not a territorial corps, belonged to nobody, for the medical profession had made it their own. At present they had over 4000 men in South Africa, exclusive of the St. John Ambulance Brigade. Not many men had been killed in action, but many had died in hospital principally from the result of infection during attendance upon the sick.

The motion having been agreed to, Sir WILLIAM BROADBENT tendered the thanks of the meeting to Princess Christian for her presence. Princess CHRISTIAN bowed her acknowledgments and the proceedings terminated with a vote of thanks to Sir William and Lady Broadbent for the use of their house.

THE WAR IN SOUTH AFRICA.

ALTHOUGH there is a comparative lull in the military news from South Africa at the present moment all that has recently reached us from the seat of war is eminently satisfactory. Lord Roberts's enveloping and converging columns are slowly but surely sweeping all opposition before them. He has a very large force at his disposal,

but considering the enormous extent and nature of the country which has to be covered and conquered, and the exceptional character of the tactics employed by the Boers, Lord Roberts has not a man too many for his purpose. Whatever might have been the temporary success attributable to the exceptional nature of the methods of the Boers, regular and disciplined troops intelligently led with a definite strategical object in view are bound to succeed eventually in accomplishing it and this is what they are now doing.

According to a recent telegram from Lord Roberts 148 officers and 3039 men of the British prisoners in the hands of the Boers at Pretoria have been released and re-armed by us with weapons captured at that place. Of the above-named, 12 of the officers and 248 of the men are in hospital. About 900 prisoners still remain in the hands of the Boers, having been removed with Mr. Kruger when he left Pretoria on June 4th.

SIR WILLIAM MAC CORMAC AT THE SALTERS' COMPANY.

Sir William Mac Cormac, Bart., K.C.V.O., was admitted to the honorary freedom of the Salters' Company on Monday last, June 18th. After the proceedings a banquet was held at which Sir William Mac Cormac made the following interesting speech:—

WORSHIPFUL MASTER, WARDENS, AND CAPTAIN PERCIVAL CLARK,—I am exceedingly sensible and appreciative of the high honour that you, Sirs, and this worshipful and ancient Company, so well known for its benevolence, its charity, and its good works, have this day conferred upon me. When I first heard of your kind intentions in my regard I can assure you that the announcement afforded me the sincerest gratification. I regard it a precious privilege and pleasure that this ancient Company should consider me in some degree fit to follow in the footsteps of such men as Huxley and Hooker and Stokes and Fergusson, who were in their time made honorary freemen of this Company. And now it is time, I think, to express to Captain Percival Clark my sincere gratitude and cordial thanks for the manner in which he has proposed the toast of the new freeman. He has been too kind and too generous to me in what he has told you, especially in what he has said in respect of my going out to the seat of war. I have only done what everyone else has done—tried to help that country of which we are all so proud when she appeared to need our help. There is no particular merit in this—it is only doing one's duty; and when it was represented to me that I could help in South Africa by my advice and the experience I had gained in other fields, when I knew that that advice and assistance would be willingly accepted by the officers of the Royal Army Medical Corps, when I also felt that my position at the head of the surgical profession in this country would add weight to any opinions I might form,—it seemed right for me to go. I felt that if I could tell those at home (and I was happily able to tell them) that all was being done to help their dear ones who were either sick or wounded that human foresight or skill could effect, then I still further and very deeply felt that I ought not to hesitate. War is no doubt a very terrible thing, but national honour and national greatness must be maintained at whatever cost. I have the strongest possible conviction that this war was inevitable, and I am convinced that history will pronounce that our quarrel has been a just one. I have said, and now repeat, that every care has been taken for our sick and wounded. The provision made for them has been unexampled in the history of war and profuse in every way, and the difficulties of transport in this immense territory have been overcome in a manner which is absolutely admirable. We have the field hospitals accompanying the fighting lines and receiving and tending the wounded in a wonderfully short time after they are hurt. We have numerous hospitals along the great lines of communication and the necessary hospital trains, and we have the general hospitals at the base and the many volunteer hospitals which the generous impulses of our people have provided. Besides these we have a fleet of hospital ships equipped with every necessary and every luxury, and we have a large staff of Army Hospital Corps and civilian surgeons and many men and women nurses. I have seen all these organisations and the working of them and can speak without stint in their praise. To mention merely the labour which this entailed I may say that I travelled over 6500 miles. Up to a recent date (June 9th) the state of affairs was the following. There were in South Africa 855 medical men attending the troops—475 officers of the Royal Army Medical Corps and 380 civil surgeons. The female nurses numbered 666 and the male nurses numbered 5668. There were 27½ field hospitals, with 100 beds in each and accommodating 2750 patients; five stationary hospitals, each with 100 beds and accommodating 500 patients; and 14 general hospitals, with 540 beds in each and accommodating 7560 patients. There were also 10 voluntary hospitals, accommodating 1800 patients. About 20,000 beds in all have been available and all these hospitals have been considerably increased. 4500 special pattern beds and bedding have in addition been sent out, and 875 are in reserve. There are seven hospital trains, four of which are at Cape Town, one at East London, and two (including Princess Christian's train) in Natal. There are 10 hospital ships, with from 150 to 250 beds in each, or about 2000 beds altogether. Some 50 tons of purely medical material go out to the Cape every week, and medicines in compressed form and bandages have been sent by millions. These bandages, I may say, would stretch to the Cape and a good part of the way back again if placed end to end. Every soldier as a part of his kit took with him two blankets, and in addition the War Office have sent out 372,964 more. Up to June 9th there have been 841 officers wounded, of whom 63 have died, showing a mortality of 7·2 per cent. 10,564 men have been wounded, with 551 deaths, or a mortality of 5·2 per cent. In other words, 93 per cent. to 95 per cent. recovered. Between 15,000 and 16,000 invalids have been sent home in the ships. Extensive organisation at home was required to deal with so large a number of sick and wounded, but very many have arrived practically fit to return to duty or well enough to go on sick furlough shortly after admission to hospital. With the assistance of the Director-General, Surgeon-General Jameson, and the medical authorities at home the abundant supply by Government of everything that could be considered useful or desirable the organisation of this huge department and the distribution of its units over an immense territory to the places where they were wanted have been accomplished without a hitch and without drawback and to the complete satisfaction of those concerned. This has depended, in the first instance, on the consummate ability, resource, and capacity for organisation of the Principal Medical Officer, Surgeon-General W. D. Wilson, and in the next upon his very able subordinates. No words of mine are needful in his praise, as the mere statement of the extent of the organisation he controls is sufficient in itself to elicit our admiration and gratitude. Nothing is more remarkable than the way in which our soldiers have recovered from their injuries and been able, in a large proportion, to return to duty. Without going into details there were amongst the wounded many of the most severe forms of injuries. Bullets traversed the brain, the chest, the heart, the abdomen, the great joints, and the largest bones, and yet complete recovery in a very large proportion followed. Many explanations have been given of this. The wonderfully pure air of the veldt is a favourite suggestion with many and all admit that antiseptic methods count for much. I am myself convinced that the main factor is the small size and high velocity of the bullet which inflicts a very small and rapidly closing wound—a clean-cut wound rather than the tearing contused form of damage caused by the much heavier projectiles formerly in use. I do not think the climate has much to do with it, for in the American war in Cuba, although the troops were decimated with typhoid fever, yellow fever, and malaria besides, the wounds inflicted by the Mauser bullets which were there used were recovered from with the same facility and in exactly the same proportion as in South Africa. I trust that I have not wearied you and that you will forgive me for having talked so much about myself. Those who are indulgent and who remember on whose behalf the toast is given will, I feel sure, recognise the difficulty of altogether excluding the subject of it. As I have already said, what I did was done from a sense of duty, and if I may judge from many kind expressions which have reached me from many different sources—and not the least kind are those which have been addressed to me to-night—my action has been rewarded by a considerable measure of success. I have myself the consciousness that at all events I did my very utmost and my very best, and none can do more

---

THE IMPERIAL YEOMANRY HOSPITAL.

BY ALFRED D. FRIPP, M.S., F.R.C.S.

Colonel A. T. Sloggett has just returned from a flying trip to Bloemfontein and he is very pleased to get back here. He

fully confirms the opinion I have already given that we are better off at this place from every point of view. The entire force under Lord Roberts has just quitted Bloemfontein and has left the town unoccupied save by a guard and the 4000 sick who are in hospital. Colonel Sloggett has not a good word to say for Bloemfontein as a site for a hospital. Dust-storms seem to be as bad there as they are at De Aar, for the ground has been trampled over for many weeks by tens of thousands of men.

We are still very full except in the two huts which, as I have already explained, we keep reserved for the Yeomanry. These are not more than half full, but almost every day a few yeomen come in. We find the patients generally prefer the tents to the huts, for, except when they are really gravely ill, they have a feeling of greater comfort and freedom when under canvas. Our field hospital has just passed up country and the *personnel* spent some hours with us before resuming their journey. We hope that they will be included in Lord Roberts's further advance.

We have managed to make quite a respectable cricket ground, the pitch of which is, of course, of matting. Fielding is possible for a few yards round the wickets, but beyond that it is very rough, for nothing has been done to the ground beyond removing boulders and karoo bushes, thus leaving an irregular and wholly un-grass-like surface. The Bedfordshire Regiment have been to play with us, and to-day a team of our men is going to De Aar to play the Civil and Military Club there. I am afraid they will not have much time, for the train which was to have taken them at 9 A.M. did not leave here till 1 P.M., and it is pitch-dark now by half-past five, sunset being at 5 o'clock and the twilight extremely short. We are still having lovely weather, about as hot in the sun as a really hot summer's day is in England, and the cold nights which set in a little while ago have ceased lately. For days together we do not see a cloud, unless, indeed, it be a cloud of locusts. These insects are always with us—sometimes a few and sometimes in large clouds, of which we have taken some excellent photographs. You will hardly believe me when I tell you that yesterday the ordinary railway-train was stopped by locusts, but it is a fact, nevertheless; for sitting on the metals, the warmth of which appears to be seductive to them, the locusts get crushed by the wheels and lubricate the surface to such a degree that the engine is unable to climb the steep incline. They settle on and around our camp—more around than on—and the other day they ate up all the little shoots of new grass and the green sprouts of the karoo bushes which have just been tempted to fresh growth by the recent rains.

The word "steal" apparently does not exist in the vocabulary of this country. Its place is always taken by "commandeer" unless a black man does it. Everybody seems to think that there is nothing wrong in "commandeering" everything he requires if he sees an opportunity, and if one man's bath towels or blankets have been "commandeered" by someone else he at once "commandeers" the first substitute for the missing articles which he comes across.

The other night a new hut which was to be filled the next day from a hospital train tempted us to push aside the 34 beds and have an impromptu dance. I think it did good to everybody who came and certainly it was greatly enjoyed by one or two local farmers and their wives and children. Wounded officers attended in their splints and bandages, and dancing was kept up until half-past ten.

The growth of the hospital goes on most satisfactorily. I think we shall be completely established by June 1st, that is to say, five months—and not six, as I stated erroneously in my last letter—from the day of the letter of Lady Georgiana Curzon and Lady Chesham which called the hospital into being.

Every Saturday our weekly convalescent train goes to Cape Town. Our specialists are often asked to give an opinion outside this hospital but they are always glad to get back again.

Deelfontein, May 7th.

I am glad to say that our hospital continues popular. The men as well as the officers say, "There never was such a place." We have had great advantages in the very fine equipment which the committee in London were able to provide us with and I think that if English people could see what a very great difference can be made in the efficiency and comfort of a military hospital by means of a little more money they would be quite willing to spend more on the medical department of the army. I hope that the war will do at least one good—that a larger sum will be voted every year for the Royal Army Medical Corps. If that were done probably it would be more easy to deal with outbreaks of infectious disease such as enteric fever, there would not be overcrowding in the hospitals, and there would be room for every sick soldier. If the presence of all the many voluntary hospitals out here does lead in the future to more money being spent on the Army Medical Department the subscribers to these voluntary hospitals will, indeed, feel that they have done a good work. With enough spent on a military hospital I think that results can be obtained as good as, or better than, in any London hospital, for not only will all the artificial aids to medical skill be present, but in this war at least a military hospital will have a great pull in the splendid climate and air of the Karoo. The things in regard to which we are worse off than in London are eggs, fresh fruit, and vegetables, but we get plenty of potatoes and onions.

To-day we have 74 yeomen in hospital. They are mostly down with sickness, but a few of them have been wounded. Among these are cases from the action near Warrenton in which the Yeomanry had their baptism of fire. I saw in one of the medical papers sent from England a suggestion that a light supper ought to be provided for men in military hospitals. I quite agree with this and it is easy to do it. We started the practice here, and I think that it is done in all the hospitals, for the interval between 5 o'clock P.M. and 7 the next morning is unduly long.

Pneumonia, as we have expected, is beginning to exert itself. Already it has carried off one of our cooks (Sergeant Phillips), who died on May 10th. He is a great loss, as he was a capital man and a hard worker, doing all the cooking of the nursing department. Several orderlies are also on the sick list, two of them from enteric fever. At present, I am glad to say, they are doing well. The first death we have had in the officers' ward occurred this week, when Lieutenant Cummings, R.A., died from enteric fever. His battery is at present at De Aar, so fortunately his brother officers were able to come over to the funeral.

A present of a plant for electric light installation has arrived, and as our bill for oil is very large we got the railway people to lend us one of their oil engines which they are not now using in the hope that we should be able to work the electric light with it and so save money. The railway people complied with our request, but on giving the engine a trial we found that the noise and smell made by it quite precluded its use near the hospital and the leakage of the electric current prohibited us from placing the engine further afield, so we have had to abandon the idea of the electric light.

Deelfontein, May 14th.

BULLET WOUNDS INVOLVING THE LUNG.

Mr. H. Temple Mursell, M.B., C.M., F.R.C.S. Edin., civil surgeon attached to the British Forces, South Africa, sends us the following interesting notes:—

A considerable number of cases of bullet wounds involving the lung have come under treatment during the war in South Africa. All those which have come within my own experience have been caused by the Mauser bullet. It has been frequently stated that the damage to the tissues inflicted by a small hard-cased bullet such as the Mauser, travelling at high velocity, is comparatively small, and within certain limits the statement appears to be correct. At the same time far more injury to the tissues is caused than would appear to be the case from the small size and innocent aspect of the wounds of entrance and exit. In those instances in which it has been necessary from any cause to follow up the track of such a bullet wound, the death of tissue around the track has been found to be much in excess of what might be anticipated. In muscular and fibrous tissues the necrosis is happily of an aseptic character in the vast majority of instances, but the resulting cylindrical cicatrix is of considerable extent and often produces more crippling than would be expected owing to the muscles and their sheaths becoming firmly bound down. In the lung a similar destruction of tissue might at first sight be predicted. But the small resistance of the lung tissue, its excellent blood-supply, and its great elasticity, apparently protect it from any serious or extensive injury in the majority of cases.

Further, although the wound from access of air and the consequent increased possibility of infection by organisms might reasonably be expected to become septic it seldom appears to do so. The immediate shock is rarely great, nor is it often that the immediate hæmorrhage is alarming. In several instances though blood was pouring from the mouth the man was able to walk up and report himself to his officer.

Hæmorrhage into the pleura in any quantity is comparatively rare, though a small amount is, in my experience, usual and is discoverable by the ordinary physical signs, but often needs careful auscultation and percussion to diagnose. The effused blood as a rule rapidly disappears and the wound in the lung as rapidly heals. In one only of the cases under my care has the intra-pleural hæmorrhage been alarming, and from its comparative rarity the case seems worthy of record.

Ten days after being wounded at Paardeberg Private P—— came under my care. He was admitted to hospital late at night in a very collapsed condition, having travelled a long distance. Beneath the left clavicle, at the junction of the middle and outer thirds, was the entrance wound of a Mauser bullet, and the exit wound was found between the ninth and tenth ribs posteriorly on the same side about two inches external to the outer edge of the erector spinæ. The left chest moved well on respiration and the percussion note was resonant except for obscure dulness at the base posteriorly. (The patient was too exhausted to try the effect of change of position.) There was absence of breath-sounds on the whole left chest except near the sternum. On the right side the breathing was harsh. On the left side with coin percussion the clanging sound was marked and audible without a stethoscope or application of the ear to the chest. Vocal resonance was in abeyance. The heart was pushed over to the right side till the apical impulse and point of greatest intensity of the first sound were one and a half inches to the right of the sternum. There were great loss of power and aching pain in the left arm and hand, but no loss of sensation and no swelling. Radial, brachial, and axillary pulses on the left side were imperceptible and the limb, though warm, was of lower temperature than its fellow. Apparently there was thrombosis of the subclavian artery in its third part, fair collateral circulation being established.

It was decided to aspirate the left chest, and this was done by means of an ordinary trocar and cannula, the trocar being inserted through the wound of exit of the bullet, between the ninth and tenth ribs posteriorly. Two and a half pints of fluid blood of dark colour and some air were removed. Chloroform was given as pus had been anticipated, the temperature having varied from 100° to 102° F. The relief to the breathing and to the circulation was great. The following day faint breath-sounds were audible over the left chest anteriorly and posteriorly except below the ninth rib, and the cardiac impulse and point of greatest intensity of the first sound were just at the right edge of the sternum. Four days later the physical signs remained the same, and there were much præcordial pain and dyspnœa. Aspiration was again resorted to in the same region with a Potain's aspirator, eight ounces of fluid blood and a large quantity of air being removed. The relief obtained was considerable, but the temperature remained febrile. Morphia was required nightly on account of præcordial pain. 14 days later, the symptoms being aggravated, chloroform was given and a portion of the seventh rib was resected in the posterior axillary line. The pleural cavity was found to be full of fibrinous strings and about eight ounces of fluid blood. A large-sized drainage-tube was inserted. From this time improvement was steadily maintained, except for a temporary relapse which was induced by the patient having to be moved from one ward to another. He was sent down to Cape Town convalescent two months after being wounded.

The conclusions to be drawn from the cases seen are:—

1. In the majority of cases relatively little immediate or remote damage results from Mauser bullet wounds of the lung.

2. The immediate hæmorrhage is usually small.

3. Intra-pleural hæmorrhage in small quantity is the rule; in large quantity comparatively rare.

4. In intra-pleural hæmorrhage of any large extent ultimate resection and drainage will in most cases be required.

5. The destruction of lung tissue is relatively small.

FIELD FORCE.—SERVICE ABROAD, SOUTH AFRICA.

Table showing the Personnel of Medical Units on the Lines of Communication.

Unit and place of mobilisation.	Names.	Remarks.
No. 13 General Hospital (Dépot R.A.M.C., Aldershot).	*Royal Army Medical Corps.* Major W. T. Swan (*a*). Lieutenant T. Biggam. " H. Richardson. " W. L. Baker. " B. R. Dinnis. " J. S. Twigg. " J. Powell. " R. L. Argles. " F. S. Walker. " W. Bennett. " P. G. Stock. *Civil Surgeons.* Mr. W. Dick. " T. H. Gardner. " E. L. Mansel. " V. E. J. McDonogh. " W. J. Moir. " W. J. Sweeny.	145 non-commissioned officers and men (including St. John Ambulance Brigade).

(*a*) Secretary and Registrar: to act as officer in charge of the unit till its arrival in Natal.

1. The Principal Medical Officer, Natal, will arrange for a Lieutenant-Colonel of the Royal Army Medical Corps in South Africa to be detailed as officer in charge of this unit.

2. The quartermaster and two warrant officers will join the unit on its arrival in South Africa.

3. 20 nursing sisters, Army Nursing Service Reserve, will be ordered to embark as early as possible after June 16th.

4. A superintendent or acting superintendent, Army Nursing Service, to be selected from the Army Nursing Service in South Africa, an extra nursing sister being included in the detail referred to in (3) to allow of the adjustment.

Medical Division, War Office, June 13th, 1900.

THE THIRTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

THE Executive Committee of the Thirteenth International Congress of Medicine announce the following entertainments offered to members attending the Congress.

On the opening day of the Congress, August 2nd, Dr. Lannelongue, the President of the Council, will give an evening fête in the name of the Government of the Republic.

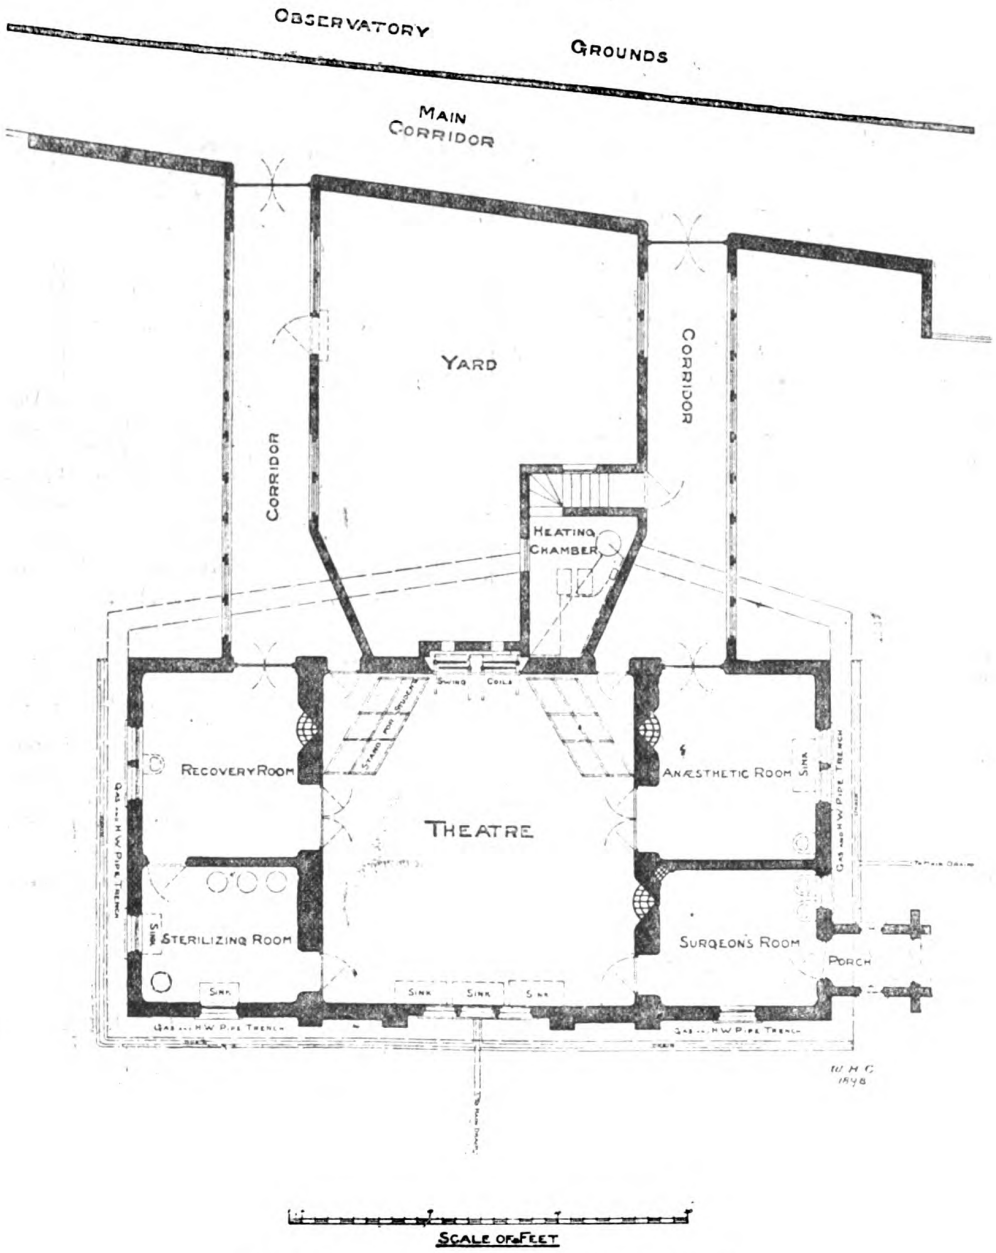
On August 3rd members will be invited to an evening fête by the President of the Congress.

On August 5th the President of the Republic will receive the members of the Congress in the Elysée.

On August 8th an evening fête will be held in the Palais du Sénat and the Gardens of the Luxembourg, where the members of the Congress will be entertained by the Bureau and the Organising Committees of the Congress. The Town Council of Paris is to be asked to give an entertainment.

Besides the above, sundry fêtes will be organised in the various sections, and it should be noted that to all these entertainments the wives, daughters, and sisters of members attending the Congress are invited. A ladies' committee has been organised for the reception of these ladies.

A NEW PUBLIC GARDEN IN THE BLACKFRIARS-ROAD.—The Bishop of Rochester on June 15th formally opened to the public the churchyard and burial ground of Christchurch, Blackfriars, which have been adapted for a public garden. Several years since a similar adaptation was considered and the Metropolitan Public Gardens Association was consulted on the question, with the result that as soon as the St. Saviour's District Board of Works had a vested interest in the churchyard and burial ground the association agreed that it would at its own cost lay out the ground for public recreation purposes. This generous promise has now been fulfilled.



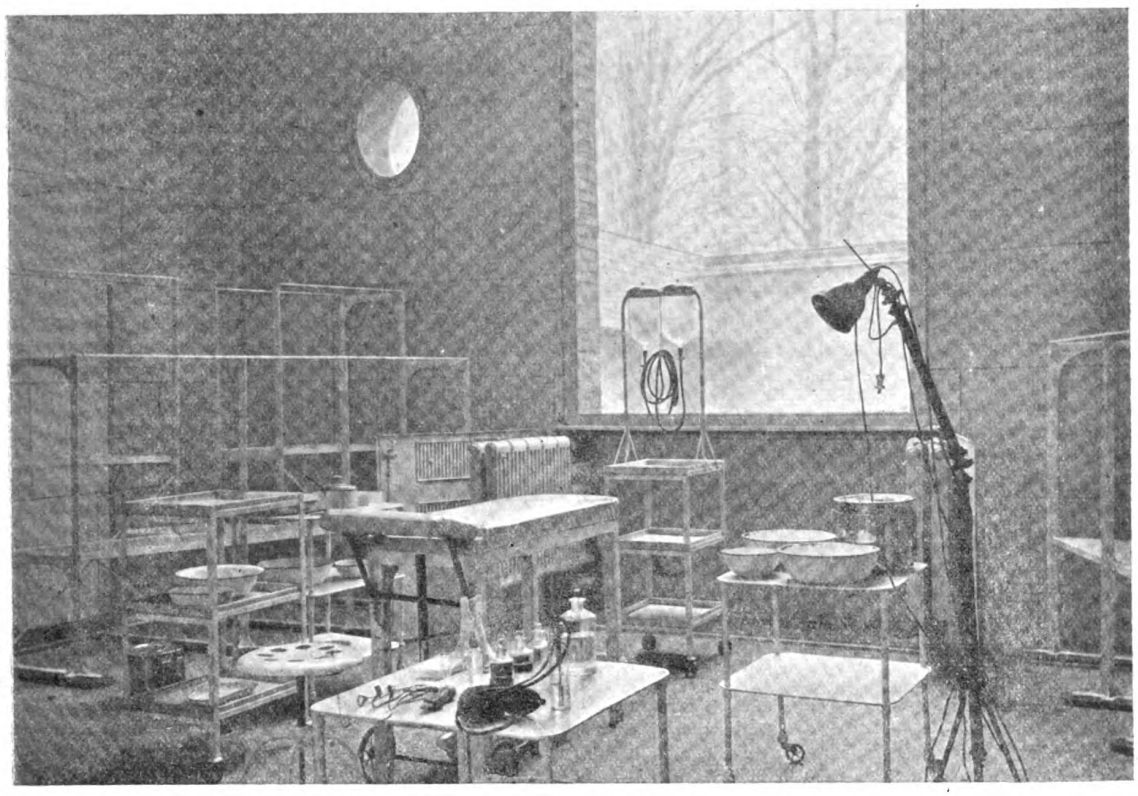
MEDICINE AT THE UNIVERSITY OF OXFORD.

THE ancient University of Oxford, although not possessing such a large and flourishing medical school as her sister Cambridge, has of late years been actively engaged in improving her facilities for giving instruction in the art and science of medicine. Among the outward and visible signs of progression two buildings stand prominently forth—namely, the new operating theatre of the Radcliffe Infirmary, which has been in working order for nearly two years, and the new laboratories for the study of pathology and the kindred sciences which are at present in course of erection.

THE NEW OPERATING THEATRE AT THE RADCLIFFE INFIRMARY.

To begin with the finished building. As will be seen by the plan (Fig. 1) the theatre is completely isolated upon three sides and only connected on the fourth to the other infirmary buildings by two corridors. The actual operating theatre occupies the middle of the building and on one side are an anæsthetic room and a surgeon's room, while on the other are a sterilising room and a recovery room. The walls of the theatre are panelled in white marble, while all the doors leading therefrom are of iron which is enamelled in white; there is an open fireplace and an electric exhaust fan in the roof. There are no shelves or brackets of any description on the walls, so that they can be washed down at any time by means of a hose. The warming is done by hot water coils which are heated

FIG. 1.



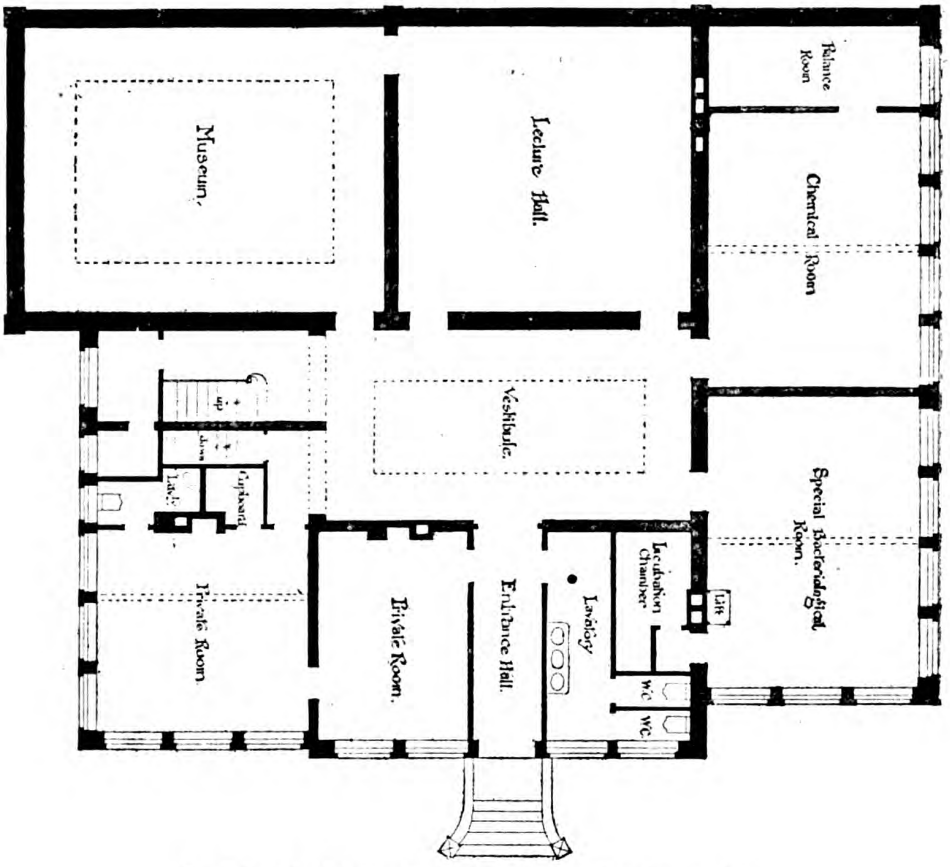
Radcliffe Infirmary, Oxford. Plan of the new Operating Teatre.

from below by gas stoves, and these coils can be, as is seen in Fig. 2, swung out from the wall so that both warming the air and removal of dust are greatly facilitated. Light is obtained from a large north window. By night, light is obtained from groups of electric lights situated in the roof above the glass ceiling, which are renewable from outside, and from a moveable standard lamp with a parabolic reflector.

The furniture is all made of iron enamelled white and includes a specially designed operating table together with the usual instrument cabinets, which are so low that the tops can be easily seen and dusted, lotion stands, surgeon's table with douche bottles, and tables for trays. These are all fitted with ball-bearing rubber wheels. Two enamelled iron stands are provided for the use of students and spectators. The anæsthetist's room is fitted as an x ray room. Current is supplied direct from the main and serves also to work a cautery and various electric lamps. The sterilising room contains two large sterilisers for the surgeons' coats and for dressings, instrument and water sterilisers, a boiler for trays and bowls, and a towel warmer. All the water-pipes are of copper and stand three inches clear of the walls. All cupboards are of enamelled iron and glass, and all sinks are of Twyford's porcelain and drain out into the open air and so into the gutter surrounding the theatre. The plug of the basins is a simple solid indiarubber ball. The floors are of mosaic and all angles are rounded. The total cost, exclusive of surgical appliances, was £3102 1*s.* 8*d.* One feature of the apparatus is an ingenious lift for patients when on the table which was devised by Mr. H. P. Symonds.

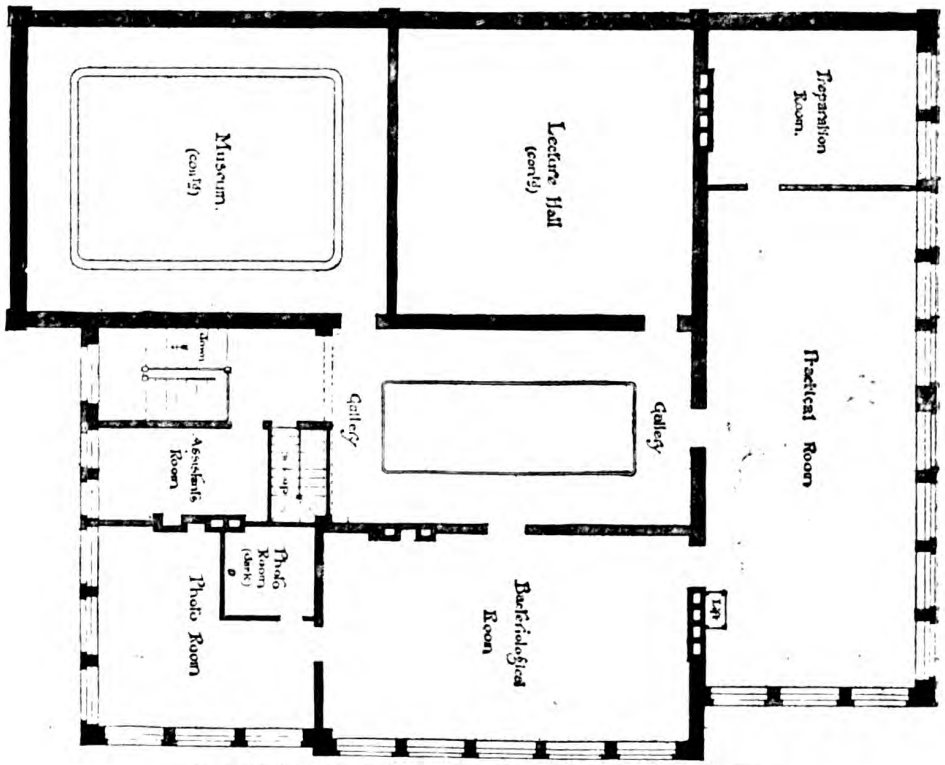
We think that the committee of management of the infirmary may well be congratulated on having obtained as perfect an operating theatre as is to be found up to the present time in any town in the kingdom. Mr. W. H. Castle of Oxford is the architect.

FIG. 2.



Interior of Operating Theatre, showing big north window, furniture, and heating coils.

THE NEW PATHOLOGICAL LABORATORIES.



The existing accommodation for the teaching of pathology in the University of Oxford having been for some time recognised to be insufficient, about a year ago the generosity of an anonymous donor provided a sum of £5000 on condition that the University added an amount sufficient to provide for and maintain an adequate department. The University accordingly last summer added a further sum of £5000 to the gift and voted for a period of five years an annual grant of £250 for maintenance. Plans of a department, prepared by Mr. J. Augustus Souttar, of 41, Bishopsgate-street, E.C., were accepted and the erection of the building is now well advanced, its completion being expected about the beginning of 1901. The site for the department is within the grounds of the University Museum to the south of the department of human anatomy. It occupies a space 75 feet by 65 feet and to the north has a yard 60 feet by 30 feet. The front elevation, in which is the main entrance, is towards the east and nearly all the rooms are lighted either from this aspect or the north. The building is of a superior red brick with stone dressings and consists of a partially sunk basement and two floors. Entering by the main door (Fig. 3) access is given to a central hall from which or from its gallery all the rooms of the department open. Running up through both floors are a lecture room 25 feet square and 22 feet high and a museum 31 feet by 25 feet and of a similar height. Besides these on the ground floor are a research room for experimental pathology 25 feet by 18 feet, and another of similar size fitted up as a chemical research laboratory. To the former is attached an incubation room and to the latter a small balance room. On this floor there also are a private room for the head of the department, a private research laboratory, lavatory accommodation, &c. On the first floor (Fig. 4) there is a large room, 43 feet by 18 feet, for the teaching of pathological histology, and to this is attached a preparation room. There is also a class-room, 31 feet by 18 feet, for practical bacteriology, a photographic room, a demonstration room, &c. In the basement of the department are a private laboratory, a dark laboratory, a large preparation room for the routine pathological and bacteriological work of the department, store room, heating apparatus room, and workshop. The basement will also contain a refrigerating room, 10 feet square and 8 feet high, kept below zero by a Hall and Co.'s carbon dioxide freezing apparatus. Arrangements have been made by which the engine necessary for this apparatus shall be capable of also driving centrifuges or other machines.

REPORT OF THE EXECUTIVE COMMITTEE OF THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON

UPON THE MEMORIAL TO HIS ROYAL HIGHNESS THE PRINCE OF WALES, K.G., FROM THE COUNCIL OF THE METROPOLITAN RADICAL FEDERATION, DATED 17TH MARCH, 1900.

THE memorial (which incorporates an article in the *Contemporary Review* by the Hon. Stephen Coleridge) after stating that the Federation represents from 40,000 to 50,000 members of working men's Radical clubs and other Radical organisations in London, and that the mass of the population by reason of the dread of entering infirmaries, caused by the social ignominy that it incurs and by the social and political disqualifications that accompany it, are absolutely dependent on the London hospitals for the skilful treatment of their more serious diseases and accidents, sets forth two matters of complaint, which are summarised as "one of the gravest scandals of our time." They are as follows:—

1. A widely spread idea that there is too much a tendency now-a-days on the part of medical doctors and students attending the London Hospitals to regard the patients that come under their hands as so much material for experiment, and the memorial in this connexion says:—"It seems to be an axiomatic truth that if experiments must be made on a living subject, the proper subject must be the person of the patient himself." An inference is drawn that the popular suspicion is based on sufficient ground.

2. That grants of money from the general receipts of hospitals are devoted to medical schools; that since the inauguration of this Fund such grants have been increased; that certain hospitals in London in receipt of large sums of money from the Prince of Wales's Hospital Fund allocate considerable grants of money from their general receipts, among which the contributions from the Prince of Wales's Fund figure, to the medical schools and to the medical training of the students attending the schools of those hospitals. And in the said article the writer after referring to your Royal Highness's statement in 1897 that there was no intention of devoting any part of this Hospital Fund towards the support of the medical laboratories, says: "Upon the committee of the Prince of Wales's Hospital Fund, therefore, there lies the heavy responsibility of disregarding His Royal Highness's clearly expressed beneficent intentions."

With regard to the first allegation the Executive Committee, under whose direction the hospitals have been recently subjected with their own accord to careful and expert inspection, are deliberately of opinion that it is unfounded in fact. No particulars are given which can be dealt with by evidence in detail. The charge is general—founded on an alleged "widely spread idea" and on what "seems to be an axiomatic truth." The committee from their knowledge of the hospitals doubt, and have reason to doubt, that any such idea is at all widely spread, and they are sure that, whether widely spread or not, it is erroneous and does grave injustice both to the medical men and the students. The axiom appears to them questionable and the inference drawn from it unjustified. Upon this loose and somewhat scandalous charge against a great profession they do not consider they are called upon to say more.

The argument of the second allegation resolves itself into this. The Fund subscribes to a hospital, a complicated organisation the main object of which is surgical and medical aid to the poor. The hospital comprises a medical school. Therefore the Fund supports the medical school. The Executive Committee loyally adhered to your Royal Highness's statement in 1897 that there was no intention of devoting any part of the Fund towards the support of medical laboratories. The honorary secretary of the Metropolitan Radical Federation has already been informed by the Executive Committee of this Fund that no grant has been made from this Fund towards the support of medical laboratories either in the case of the Middlesex or any other hospital, and that all hospitals applying are considered according to their needs and merits as institutions for the relief of the suffering poor. The utmost that can be made of the charge is that some minute unascertained portion of a grant for general purposes may have percolated under the administration of the hospital concerned into a medical school or laboratory. But even this has been guarded against, and so far as the committee can ascertain no such percolation has actually occurred.

The awards made by this Fund to the hospitals have been made with certain conditions, following as nearly as possible the recommendations of the visitors who have inspected and reported upon them, and these awards and the objects for which they were made are stated in the annual reports of the Fund and have also been published in the public press. In no case can there be found in these reports an award given for a medical school or laboratory.

Nor can it be fairly said that the hospital authorities have in fact used any part of such grants for medical schools and laboratories. It is alleged that certain payments in connexion with the schools have been increased since this Fund was started, but even if this be so it by no means follows that such increases were made in consequence of the help given by this Fund to the hospitals in question. In three cases (Middlesex, London, and St. Mary's) out of the four quoted the receipts of these hospitals, excluding any grant from this Fund, were considerably over £40,000 more in 1897 than in 1896. These hospitals had, therefore, much greater resources out of which larger grants could have been made to the schools quite irrespective of any grants from this Fund. In the remaining case, that of Guy's Hospital, where £116 is mentioned as being paid for the school in 1896 and £595 in 1897, the hospital's receipts, including £8000 from this Fund, were less than those of 1896, thus giving a result antagonistic to the theory of greater funds greater help to the schools. There is no reason for supposing that Guy's, any more than the other three hospitals, used the contributions from this Fund, or any part of them, for the purposes of the medical school or the laboratory. It is to be observed that, accepting as correct the sum stated to have been for the benefit of the schools, they do not rise or fall in proportion to the grants from this Fund, and have from this point of view no co-relation with such grants; indeed, it is quite clear that the amounts paid in connexion with the schools, which bear only a very small proportion to the total annual expenditure of the hospitals, are determined by factors other than the receipts from the Fund. In none of the hospital accounts does it appear that any part of the grant from this Fund has been allocated to the schools. In the case of the Middlesex Hospital, which is given special prominence in the article, £600 is disbursed in 1897 in connexion with the school, forming part of a total annual expenditure of £30,000. The grant from this Fund in 1897 is quoted in the article as £1000, but as a matter of fact the amount was £2925. Looking at the varied items of receipts, it is not fair and reasonable to infer that because money from this Fund is included in such receipts any part of it must necessarily have been used for the school, especially when it is shown that among the other receipts there are annual dividends of £6615, of which £2076 are for the Cancer Fund. It would be more fair and reasonable to assume that a portion of such dividends is properly available for school purposes, and this presumption is borne out by a recent statement in the public press by Sir Ralph Thompson, who refers to some bequests to this hospital which are given not only for the cure and care of patients suffering from cancer, but also for the purpose of investigating and promoting a general knowledge of treating it.

In administering this Fund the committee have endeavoured in all cases to aid the hospitals in the manner best suited in the case of each hospital to benefit the sick and suffering poor of London, and they have no reason to believe that the eminent authorities who are associated with the large and important hospitals that have medical schools have done otherwise than act to the best of their ability in promoting the highest interests of the hospital patients.

THE THAMES CONSERVANCY.

THE general report of the Conservators of the river Thames for the year 1899 has recently been published. Of the public bodies which are engaged in work directly or indirectly bearing on the health of the people of London not one, perhaps, carries out the duties committed to it with more thoroughness and less ostentation than the Thames Conservancy Board. It is probably realised by few people that the purification of the river is only one amongst a number of important duties which the Conservators have to perform, a great part of their work being the protection of the navigation of the river, both above and below London.

The report, which is merely a brief summary of the work which has been done during the year, is divided into three parts, which deal respectively with the lower river, with the upper river, and with the prevention of pollutions. During last year the Conservators completed the deepening of the river channel from Blackwall to the Nore, and also carried out dredging operations between Crayford Ness and the Royal Albert Docks and also at Mucking Flats. A survey was carried out in the neighbourhood of Tilbury Docks, and the results of the investigation showed an improvement in the channel of the river at this point. Above London Bridge it is of interest to note that a survey has been completed as far as Vauxhall Bridge and that the result shows an improvement of from one to two feet in the depth of the river channel. The Conservators have made provision for the prevention of the discharge of refuse from the hoppers which are used for the conveyance of mud to the sea, the mooring-places and landing-places on the river have been maintained in order, and some additional moorings have been laid down. During the year 55 vessels were raised by the Conservators, and of these eight were steam-vessels and 47 sailing-vessels and barges. In the upper river above Staines dredging operations have been necessary to maintain the navigable channel, the tumbling-bay at Old Windsor weir has been extended on the Berkshire side and the crest of the existing tumbling-bay has been lowered, and the back-water below the weir has been deepened. A new weir and flood channel are in process of construction at Sonning.

We mention briefly the things which have been done on the river to give some idea of the enormous extent of the task carried out by the Thames Conservators. The most important part of their duties from a sanitary point of view is that which has to do with the prevention of pollution of the river in carrying out the extensive powers which were conferred under the Act of 1894 (57 & 58 Vict., cap. 187). The attention of the Conservators has been given chiefly to towns and large centres of population and to those places where sewage farms and works are situated. In all cases all the effluents have been frequently tested by the Conservators' analyst. During the year 1899 the pollutions from 17 towns and villages, containing together a population of over 36,000, were diverted from streams which were tributaries of the Thames. In those cases in which local authorities still cause pollution pressure has been continuously exercised and in most instances the sanitary authorities are taking measures to fulfil the requirements of the Conservators and have either submitted, or are preparing, drainage schemes for submission to the Local Government Board. Amongst other places, Witney, Thame, Aylesford, and Marlborough have commenced drainage works which will involve a considerable outlay on the part of each of those places. It was found necessary to institute legal proceedings in 14 cases in which the authorities did not comply with the requirements of the Conservators. As a result of these prosecutions four convictions were obtained, three cases were adjourned by the magistrates, and seven were withdrawn on the undertaking that the defendants would take immediate measures to carry out the necessary work. In the case of scattered farms, houses, and factories pollution has been diverted in no less than 197 instances. In regard to the pollution from houseboats and barges the powers of the Conservators have been carried into effect; these vessels have been watched by the inspector and no case of pollution has been discovered. This is a satisfactory improvement. It may be remembered that some years ago the condition of the river at Henley was most insanitary owing to the pollution from houseboats and THE LANCET at the time found it necessary to direct attention to the state of things which then existed.

The report on the flow of water in the Thames calls for notice. During the months of July, August, and September last the Conservators record that the average flow over Teddington weir was below the 200,000,000 gallons a day which they consider to be the minimum amount which should be left after the metropolitan water companies have drawn their supplies. In October the daily average rose to something over 250,000,000 gallons daily, in November to over 900,000,000 gallons, and in December it again fell to about 475,000,000 gallons daily. The fact that for three consecutive months during last year the daily average flow of water over Teddington weir was below that which is considered by the Conservators to be the minimum quantity which should flow down to the lower reaches of the river is a point of considerable importance. It emphasises the fact that too much water is already withdrawn from the Thames during periods of drought by the metropolitan water companies, and it is the strongest possible argument against allowing any further removal of water from the Thames during periods of drought. There is, of course, no doubt that if the whole of the natural flow of the Thames were allowed to pass down the river the expense of keeping open the navigable channels of the lower river would be considerably less than it is at present. The increase of outlay which is rendered necessary by the abstraction of so large a quantity of water for drinking purposes, therefore, causes an outlay in dredging which would not otherwise be needed. The flood-water which now passes down in large quantities thoroughly flushes out the lower river occasionally, but if this flood-water were taken by reservoirs in the Upper Thames it would necessarily follow that there would be a largely increased expense in dredging the lower river.

The work done by the Conservators for the purification of the upper river has been very thoroughly carried out and the improvement which has taken place in the purity of the water has been enormous. It must not be thought, however, that this purification of the upper river cleanses to any very marked extent the Thames in London. Unfortunately, during periods of drought by far the greater proportion of water which would naturally flow down through London is taken for drinking purposes and the water which is between the bridges is more affected by the state of the lower river than by that of the water which flows down from above.

THE ANNUAL DINNER OF THE INDIAN MEDICAL SERVICE.

UNDER the chairmanship of Sir TREVOR LAWRENCE, Bart., the officers of the Indian Medical Service held their annual dinner at the Hotel Cecil on June 14th. After the usual loyal toasts had been proposed and honoured that of the "Sister Services" was given by Surgeon-General C. SIBTHORPE, I.M.S. He mentioned in the course of his speech that a professor of one of the Scotch medical schools had decried their brother officers in the Army Medical Service. The professor thought that some of the officers had not as much experience as they ought to have and were not up to the standard, but he (Surgeon-General Sibthorpe) found that the standard of education was extremely high and he had never found them wanting in their professional work.

Sir HENRY NORBURY, K.C.B. (Director-General of the Medical Department of the Royal Navy), in responding to the toast, said that it was not often that the naval medical officers were associated with the Indian Medical Service, but it was not impossible that they might soon find themselves working together again as an outcome of what was then happening in China.

Surgeon-General JAMESON, C.B. (Director-General of the Army Medical Service), also replied to the toast of the "Sister Services." He said that they had at the present moment in South Africa no fewer than 8000 attendants belonging to the medical service for the care of the troops. He was happy to state that up to the present moment they had been able to meet every demand for *personnel* and *matériel* made on them. They had also made a new departure by employing in South Africa a large number of civilians in the bearer companies, thereby relieving a corresponding number of regular bearers who were more usefully employed in the field hospital. They had also taken into their service from time to time a considerable number of special bearers, which had proved a most useful plan. When Sir Redvers Buller left the railway and marched 30 miles to fight the battle of Spion Kop he engaged 1600 civilians that he picked up on the spot, and through their aid he was able before nightfall to remove every wounded man from the field of battle and to have them comfortably in hospital before breakfast time the next morning. They had now the intention at home of making some further arrangements for the care of the men invalided from the seat of war. This was rendered necessary because almost every case in which it was thought the voyage home would be beneficial was being returned to this country. They were receiving in England a very large number of these patients every week and that put their hospitals to a severe strain. They had not up to the present moment required to make use of the civil hospitals. Surgeon-General Jameson then referred

to the effect of inoculation for enteric fever. It was difficult, he said, at this period to get accurate statistics, and it was quite clear that a very large number of figures must be collected before a final opinion could be arrived at. Everyone, therefore, would recognise how difficult it was to form any sort of general conclusion. They had read a good deal in the daily papers about the enormous amount of enteric fever among the troops in South Africa, but he would remind them that it was not so bad as it was in the Afghan war.

The CHAIRMAN proposed the toast of "The Guests" and referred to the good feeling which existed between the civilians and the military medical men in South Africa. The toast was responded to by Dr. W. S. CHURCH, the President of the Royal College of Physicians of London, who said that the profession owed a debt of gratitude to the Indian Medical Service. The names of Manson and Ross were familiar to all in active work and medical men looked to that service for information in regard to diseases concerning which practical experience was not obtainable in England.

Dr. FREDERICK ROBERTS, the President of the Medical Society of London, proposed "The Indian Medical Service" and the toast was replied to by Surgeon-General Sir JOSEPH FAYRER, Bart., who referred to the very early days of the service and the influence of Broughton and of Hamilton.

The proceedings terminated with votes of thanks to the chairman and to Mr. Freyer, to whom, as secretary, the success of the dinner was largely due.

The following is a list of the names of the guests and members who were present:—

Guests.—Dr. Church, President of the Royal College of Physicians of London, Sir Henry Norbury, K.C.B., Surgeon-General J. Jameson, C.B., Dr. Pavy, President of the Royal Medical and Chirurgical Society, Dr. F. Roberts, President of the Medical Society of London, Surgeon-General T. Walsh, A.M.S., Mr. Austin Low, honorary treasurer. Dr. Dawson Williams, Editor of the *British Medical Journal*, and Mr. Thomas Wakley, jun., Joint Editor of THE LANCET.

Members. — Dr. W. S. Playfair. *Surgeon-Generals:* A. C. C. De Renzy, C.B.; Sir J. Fayrer, Bart., K.C.S.I., F.R.S., W. R. Hooper, C.S.I., W. R. Rice, C.S.I., C. Sibthorpe, C.B., and L. D. Spencer, C.B. *Colonels:* W. Cates, D. E. Hughes, J. C. Penny, D. O'C. Raye, W. H. Roberts, Sir George Thomson, K.C.B., B. Williamson, and W. A. S. Wynne. *Lieutenant-Colonels:* H. Atkins, F. C. Barker, W. R. Browne, W. H. Cadge, A. M. Crofts, C.I.E., A. Crombie, G. W. P. Dennys, P. J. Freyer, T. Grainger, J. Ince, D. F. Keegan, I. B. Lyon, C.I.E., G. Massy, T. Mulroney, G. Ranking, G. D. Riddell, J. Scully, T. Skardon, G. S. Sutherland, W. H. Thornhill, C. J. H. Warden, D. Warliker, A. H. Williams, and H. P. Yeld. *Majors:* W. Alpin, F. Carlea, R. H. Castor, J. W. Caldwell, F. C. Clarkson, F. J. Drury, E. Dobson, A. S. Faulkner, B. B. Grayfoot, and S. Hassan. *Captain:* J. Fisher.

ARMY MEDICAL REPORT FOR 1898.[1]

III. (CONCLUDING NOTICE.)[2]

IN concluding our remarks on enteric fever among the British troops serving in India and subtropical climates we may briefly advert to its relative prevalence among officers and women and children. The ratio of admissions for enteric fever to strength among officers serving in India was 40 per 1000 in 1898 (which is a rather higher ratio than that among the rank and file), while the death-rate was 8·08. The cases were distributed over as many as 33 stations. The admission rate among the women for enteric fever was 12·2 and the death-rate 4·81, and among the children (with an average strength of 5592) the admission rate was 7·0, and the mortality rate 0·54 per 1000. It would appear, therefore, that officers suffer about equally with the men from enteric fever, notwithstanding that the hygienic conditions under which they live are presumably better and their risk of contracting the disease through the medium of native bazaars, liquors, and drinks one would think less than among the men, while the consumption of water and milk among women and children would certainly not be less, but probably more, than among the men. The problem of determining what is the exact causation of enteric fever among the European residents in India is a very difficult one which has still to be satisfactorily worked out, especially when it is borne in mind that the amount of prevalence of this fever among the native troops, jail population, and the native population generally is apparently so insignificant as compared with what it is among the Europeans.

With regard to venereal disease in India it is still too early to form any reliable opinion as to the effect of the measures which have been recently adopted for its control; still, it is satisfactory to learn that the Principal Medical Officer reports that the admission rate for these diseases in 1898 shows 136·4 fewer admissions to hospital per 1000 than in 1897, nor is this to be accounted for by the employment of men on field service. The reduction is, in his opinion, attributable to the influence of other measures, such as the new cantonment rules, the putting of bazaars out of bounds, and the continuance of the treatment of men after their discharge from hospital instead of frequently re-admitting them into hospital for that purpose.

The number of surgical operations recorded for the year as having been performed among the European troops serving in India amounted altogether to 496, of which 476 were primary and 20 secondary. Death followed in 67 cases of the former and two of the latter. The majority of the operations were, however, of a minor character. It may be mentioned that of 104 cases of abscess of the liver operated upon in 1898 46 were successful, 57 ended fatally, and one was under treatment at the end of the year.

Turning to the appendix, which is the most interesting part of the volume to the professional reader, the report itself being more especially intended for the information of Parliament and lay readers, we find a good selection of papers of varying interest. The first is one upon the Progress of Hygiene for the Year 1899 by Colonel J. Lane Notter, Professor of Military Hygiene at the Netley Army Medical School. These reports are always useful and instructive because they give a short and condensed *résumé* of what has been going on in the way of sanitation and practical hygiene during the year. Under the heading of Literature, for example, Professor Notter very briefly describes and sums up the contents of a large number of books which have been published on the subject of hygiene during the year. This is followed by a section on the work of societies with a succinct account of the proceedings and the papers read at them, and by another section devoted to special points of hygiene. The article, as a whole, gives medical officers what they want to know and is, at the same time, calculated to save them a good deal of labour and the inconvenience and expense of having to procure and carry about with them a number of books instead of selecting such only as they really need or desire to have.

The article containing a list of operations performed at Netley during the year 1898–99, with a return of the wounded invalids and surgical cases treated in the Royal Victoria Hospital, accompanied by descriptive accounts, with notes and comments upon these cases, is a conjoint production by Colonel W. F. Stevenson, M.B. Dub., R.A.M.C., Professor of Military Surgery, and by Major W. Dick, M.B. Edin., R.A.M.C., the Assistant Professor of the Army Medical School, Netley, and it is well worth reading. Some of the cases and the operative procedures adopted are both interesting and instructive. Colonel K. McLeod, M.D. Edin., LL.D. Aberd., I.M.S., Professor of Clinical and Military Medicine at the same school, deals with the patients treated in the medical division of the hospital. One of the cases he describes is one of splenic anæmia which followed an attack of Mediterranean fever to which it was apparently a sequela; another is a case of syphilitic cachexia and paroxysmal hæmoglobinuria associated with Raynaud's disease. Surgeon-General W. Taylor, C.B., contributes a report of the Medical Transactions of the Nile Expeditionary Force to Khartoum in 1898. Enteric fever and dysentery prevailed to a considerable extent among the troops in the Soudan. The report gives a brief account of the number and character of the wounds received in action and some useful observations on the best type of building

[1] Army Medical Department. Report for the year 1898. With Appendix. Vol. xl. London: Printed for Her Majesty's Stationery Office by Harrison and Sons, St. Martin's-lane, Printers to Her Majesty. 1900. Price 2*s.* 6*d*

[2] The two previous notices were published in THE LANCET of May 12th, 1900, p. 1384, and June 9th, 1900, p. 1675, respectively.

for hospitals, the most serviceable unit for field hospitals and many points connected with medical administration in the field. There are several other papers connected with field operations in West Africa; an elaborate report on enteric fever in Pietermaritzburg; and one on the method of preparation and control of anti-venomous serum (antivenene), with experiments by Major D. Semple, M.D. R.U.I., R.A.M.C., Assistant Professor of Pathology at Netley, who, accompanied by Major R. W. S. Lyons, M.D. R.U.I., I.M.S., and Surgeon O. W. Andrews, M.B. Durh., R.N., proceeded to the Pasteur Institute at Lille and placed themselves under a course of instruction by Dr. A. Calmette and his assistant, M. Guérin. The experiments and observations were most carefully conducted and the report is compiled with much scientific detail. Major Semple has also another paper on matters that came under his observation at the Pasteur Institute in Paris.

ASYLUM REPORTS.

Surrey County Asylum, Brookwood (Annual Report for 1899).—The average number of patients resident in the asylum during the year amounted to 1080 and comprised 437 males and 643 females. The total cases admitted during the year were 260 patients, of whom 121 were males and 139 females. The greatest number resident on any one day was 1118, and the least was on the last day of the year—viz., 999. Mr. James E. Barton, the medical superintendent, states in his report that "for the greater part of the year the asylum continued in a very overcrowded state and sleeping accommodation had to be provided on the floor. ..... Considering the crowded state of the wards and dormitories the general health of the asylum has been good throughout the year. Diarrhœa was more or less prevalent and five cases of typhoid fever occurred, one of which ended fatally. Influenza was very rife and many of the patients and staff suffered. Considerable inconvenience was caused by many attendants and nurses being off duty for lengthened periods—the debility following the attack rendering leave of absence to recuperate necessary." For a short time during the summer much anxiety and inconvenience were caused by the deficiency of the water-supply. For two days in August the institution was practically without water and for some time the canal water had to be used for laundry and flushing purposes. Of the 260 patients who were admitted during the year 123 were brought from their own homes and 109 came from workhouses; 11 were transfers from other asylums; 45 were re-admissions and included a male criminal lunatic who on expiration of sentence was transferred from the private to the pauper class. "The general type of the admissions was very unsatisfactory; the majority suffered from chronic insanity and many were dangerous to themselves or to others. Hereditary predisposition or congenital defect existed in nearly 34 per cent. ..... In addition to hereditary and congenital defect the chief causes of insanity were previous attacks, mental worry, and alcoholic intemperance. In 10 cases the insanity followed an attack of influenza, the chief feature in these cases being depression, apathy, and debility." During the year 114 cases—viz., 45 males and 69 females—were discharged as recovered, or 10·5 per cent. of the average number resident. The deaths during the year numbered 100, a proportion of 9·25 per cent. on the average population. This is a fairly low rate considering the number of feeble old people in the asylum. 11 died within a month of admission. Post-mortem examinations were made in 70 cases. Of the deaths five were due to senile decay, six to influenza, seven to cardiac disease, 10 to general paralysis of the insane, 12 to apoplexy and organic brain disease, and 18 to pulmonary phthisis. Four females and three male patients sustained serious casualties, all being with one exception fractures caused by accidental falls or struggles with other patients. The new bathroom for the female division of the main building and the bathrooms and lavatories for the medical officers were completed during the year. Many changes have occurred in the asylum staff, several of the best attendants, who were army reservists, having left to rejoin their regiments. These were granted leave of absence, and their posts are kept open for them. The new drainage system has been completed, with the exception of connecting the asylum drains with the district council's sewers at Woking, which will shortly be done. The Lunacy Commissioners in their report draw attention to the overcrowded state of the asylum and suggest the provision of an incinerator for the destruction of rubbish, as such an addition to the works would be most useful for the destruction by fire of typhoid fever patients' excreta which are now buried after treatment with carbolic acid.

Leicestershire and Rutland Lunatic Asylum (Annual Report for 1899).—The population of the asylum during the year consisted of 493 patients, of whom 232 were males and 261 were females. The admissions for the year amounted to 90 patients, of whom 48 were males and 42 were females. 16 of these—viz., 11 males and five females—were re-admissions. Mr. Rothsay C. Stewart, the medical superintendent, states in his report that of the admissions 22 patients were known to have had previous attacks and hereditary tendencies to insanity were traced in 17 cases. The epileptics numbered 12 and the general paralytics numbered six among the admissions. "22 cases were between the ages of 65 and 84 and in my opinion a fair proportion of these were more fit for a workhouse than an asylum." During the year 29 patients were discharged as recovered, 15 of these being males and 14 being females, or a total of 5·8 per cent. of the average number resident. The total number of deaths during the year was 62 and comprised 32 males and 30 females, or 12·5 per cent. of the average number resident. Of the deaths two were attributed to influenza, three to pneumonia, one each to colitis and diarrhœa, three to epilepsy, five to general paralysis of the insane, seven to cerebral softening or hæmorrhage, eight to cardiac disease, 11 to senile decay, and 12 to pulmonary phthisis. The mortality from phthisis is the highest in the tables given regarding the causes of death. There were five accidents involving fractured bones, but none of them ended fatally. Two female patients, both married women, gave birth to children while in the asylum. One of these has since gone out as recovered. Two male patients escaped during the year, one being subsequently recaptured. During the month of April, 1899, there was a severe epidemic of influenza among the staff, especially on the female side. At the outbreak of the war several of the attendants who had received orders as reservists left to rejoin their regiments and the work on the male side has had to be carried out with much difficulty. "Their places are kept open for them in case they wish to rejoin us, and the committee passed a resolution to pay half the wages to the wife of every reservist so long as he was on active service." The site for a new asylum at Narborough, consisting of 182 acres, was visited in January, 1899, by the Commissioners in Lunacy, and they gave consent to its purchase under certain conditions. Arrangements have been made with the borough authorities for the purpose of securing an efficient water-supply to the new asylum, and two houses have been purchased which will serve as residences for some of the staff. The profit derived from the farm and garden amounted to £330 in round figures. The aggregated expenditure on building and repairs accounts for the year has been £1691. The Lunacy Commissioners in their report state that the case-books and medical records are admirably kept, the former being illustrated by excellent photographs of the patients taken on their admission and discharge.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Birmingham Urban District.—The estimated population of Birmingham for 1899 was 514,956, but Dr. Alfred Hill thinks that this may be some 22,000 too little. The marriage-rate for the year in question was 20·8 and the birth-rate 34·3 per 1000, only six of the great towns having a higher birth-rate than Birmingham. As regards death-rate Dr. Hill has recently adopted a system by which each death will, as far as is practicable, be referred to its own ward and locality, and by this means much more reliable data will be procured. For instance, during 1899 more than 1000 deaths were referred to the precise wards and streets from which the

deceased came instead of appearing as heretofore under the heading "Institutions." The general death-rate of the city after having been corrected in the above sense was for 1899 20·5 per 1000, and in reference to the relation between the insanitary conditions associated with poverty and the death-rate Dr. Hill furnishes the following very instructive figures:—

Proportion of houses at 3s. 6d. per week or less.	Death-rate per 1000.
None	17·1
From 0 to 25 per cent.	26·1
From 25 to 50 per cent.	32 7
Over 50 per cent.	37 6

When, too, this aspect of the question is examined in more detail it is found that the same general principles obtain. Although all these figures tend to show that poverty is *per se* a cause of high mortality Dr. Hill rightly points out that material improvement can be brought about by a rigorous supervision of the conditions under which the poor live; indeed, it may surely be laid down as one of the most important duties of the officers of sanitary authorities to help the poor who for many obvious reasons are unable with chances of much success to help themselves. In Birmingham the health visitors are able, it appears, to do most valuable work in this direction, and it must be a source of much satisfaction to Dr. Hill to be so well provided in this respect. As regards infantile mortality, the figures for 1899 are again high, no fewer than 193 infants out of every 1000 born having perished before the first anniversary of their birthday. There was an outbreak of diphtheria in connexion with certain schools during 1899 and as a result the schools had eventually to be closed on two occasions, the first closure having failed to check the outbreak. Enteric fever, too, became epidemic in the fourth quarter of last year, the number of cases, 417, being far in excess of those notified during the same quarter of recent years. Personal infection seems to have played a prominent part in the outbreak, no fewer than 72 cases being attributed to this agency. Moreover, unrecognised cases seem also to have been operative. So much was Dr. Hill impressed with the infectivity of enteric fever that he has since prevailed upon the Town Council to provide hospital accommodation for the isolation of cases of this disease. There can, we think, be little doubt that the element of direct infectivity has not even yet received due recognition at the hands of the medical profession as a whole. Diarrhœa and enteritis claimed as many as 1411 victims during the year, and Dr. Hill's investigations brought out the prominent part which filth and overcrowding bore in the causation of these diseases. There was also a far greater incidence of diarrhœa deaths in houses provided with "pan" closets than in those provided with water-closets. Notwithstanding this association we learn that but 199 pan privies were converted into water-closets during 1899, while there are some 31,000 of these unwholesome arrangements still existing in Birmingham. The medical officer of health suggests that with a view of bringing about improvement the council should bear a portion of the cost of replacing these structures. In his capacity of city analyst Dr. Hill reports that there is a steady decrease in the use of boric acid as a milk preservative, but that the use of formic aldehyde is steadily increasing. It is, too, of interest to note that the use of preservatives and the question of adulteration tend to go hand-in-hand. The amount of boric acid found ranged from 21 to 126 grains per gallon.

Edinburgh Sanitary District.—Sir Henry Littlejohn, the medical officer of health of this district, estimates its population to the middle of 1899 at 298,927, although, in common with all his colleagues, he is careful to point out that the possible revelations of the forthcoming census should not be lost sight of. The birth-rate was 27·49 and the general death-rate was 19·2 per 1000. There were three deaths from typhus fever, but these are to be regarded as a legacy from the 1898 outbreak. Accompanying Sir Henry Littlejohn's report are some capital charts illustrating the prevalence and mortality of different infectious diseases. As regards the local distribution of enteric fever and diphtheria, after discussing the incidence of each disease upon the Old and New Town respectively, he points out that on a basis of the statistics for 1898–99 "the chance of taking typhoid fever among every 10,000 of the population in the Old Town, New Town, and Southern districts may be expressed as about 13, six, and seven respectively. Whereas in regard to diphtheria the chances are, in the same order, six, 11, and 10," facts which illustrate, Sir Henry Littlejohn thinks, that in so far as Edinburgh is concerned "the class of property and of inhabitants in which diphtheria on the one hand and typhoid fever on the other are most prevalent is totally different." The question of milk as a source of infection is dealt with somewhat fully in the report before us by virtue of the fact that the circumstances connected with three outbreaks of scarlet fever and one of enteric fever were suspicious of milk-borne infection, although the evidence in certain of the cases was, as Sir Henry Littlejohn observes, insufficient for a definite conclusion to be arrived at. The responsibilities and difficulties of a medical officer of health in connexion with what may be milk-borne epidemics or outbreaks are well brought out by Sir Henry Littlejohn. The hardship associated with the stoppage of a supply cannot be lightly inflicted by a conscientious officer, and yet even the suspicion that the milk may be operative as a carrier of infection must cause him much anxiety. The common habit of milk vendors of mixing the milk derived from different farms and of purchasing an additional supply if their own runs out introduces many complications into etiological investigations which would otherwise be often relatively easy of solution.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 7006 births and 4004 deaths were registered during the week ending June 16th. The annual rate of mortality in these towns, which had been 18·4, 17·7, and 16·8 per 1000 in the three preceding weeks, rose to 18·0 last week. In London the death-rate was 17·4 per 1000, while it averaged 18·4 in the 32 provincial towns. The lowest death-rates in these towns were 9·4 in Cardiff, 11·3 in Norwich, 12·0 in Nottingham, and 12·7 in Croydon; the highest rates were 22·0 in Huddersfield, 22·9 in Sheffield, 23·7 in Liverpool, 24·8 in Salford, and 25·2 in Manchester. The 4004 deaths in these towns included 427 which were referred to the principal zymotic diseases, against 423 and 386 in the two preceding weeks; of these 138 resulted from measles, 108 from whooping-cough, 65 from diphtheria, 61 from diarrhœa, 29 from "fever" (principally enteric), and 26 from scarlet fever. The lowest death-rates from these diseases last week occurred in Plymouth, Cardiff, Swansea, Leicester, Bradford, and Gateshead; and the highest rates in Derby, Manchester, Salford, Blackburn, Huddersfield, and Hull. The greatest proportional mortality from measles occurred in Huddersfield, Leeds, Hull, and Sunderland; from scarlet fever in Blackburn; from whooping-cough in Croydon, Wolverhampton, and Oldham; and from diarrhœa in Birkenhead, Burnley, and Huddersfield. The mortality from "fever" showed no marked excess in any of the large towns last week. The 65 deaths from diphtheria included 28 in London, nine in Sheffield, four in Manchester, and four in Leeds No fatal case of small-pox was registered last week in any of the 33 large towns. There were 15 small-pox patients under treatment in the Metropolitan Asylums Hospitals on Saturday last, June 16th, against 5, 7, and 11 at the end of the three preceding weeks; eight new cases were admitted during the week, against four in each of the two preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1766, against 1784, 1760, and 1754 at the end of the three preceding weeks; 210 new cases were admitted during the week, against 216, 194, and 203 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 266 and 268 in the two preceding weeks, declined again to 257 last week, but were 29 above the corrected average. The causes of 43, or 1·1 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Birmingham, Bristol, Leeds, and in 15 other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, Salford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·6 and 18·3 per 1000 in the two preceding weeks, rose again to 19·9 per 1000 during the week

ending June 16th, and was 1·9 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 17·2 in Greenock and 17·9 in Leith to 21·9 in Aberdeen and 27·0 in Perth. The 616 deaths in these towns included 23 which were referred to measles, 22 to diarrhœa, 21 to whooping-cough, six to scarlet fever, four to diphtheria, and two to "fever." In all 78 deaths resulted from these principal zymotic diseases, against 57 and 73 in the two preceding weeks. These 78 deaths were equal to an annual rate of 2·5 per 1000, which was 0·6 per 1000 above the mean rate for the same period in the 33 large English towns. The fatal cases of whooping-cough, which had been 25 and 17 in the two preceding weeks, rose again to 21, of which 17 occurred in Glasgow. The deaths from measles, which had been 16 and 19 in the two preceding weeks, rose again last week to 23, and included 14 in Glasgow and four in Edinburgh. The fatal cases of diarrhœa, which had been 25 and 7 in the two preceding weeks, rose again last week to 22, of which 12 were registered in Glasgow and five in Dundee. The deaths from scarlet fever, which had been one and six in the two preceding weeks, were six again last week and included two in Edinburgh. The fatal cases of diphtheria, which had been five, four, and three in the three preceding weeks, rose again to four. The two deaths from "fever" showed a marked decline from the number in the preceding week and were all registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 94, 104, and 106 in the three preceding weeks, declined again to 101 last week, and were 14 above the number in the corresponding week of last year. The causes of 28, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·9 and 23·1 per 1000 in the two preceding weeks, rose to 23·8 during the week ending June 16th. During the past four weeks the death-rate in the city has averaged 23·5 per 1000, the rate during the same period being 16·7 in London and 18·6 in Edinburgh. The 160 deaths registered in Dublin during the week under notice were fifteen above the number in the preceding week, and included six which were referred to the principal zymotic diseases, against five, three, and 10; of these, two resulted from diphtheria, two from "fever," one from scarlet fever, one from diarrhœa, and not one from small-pox, measles, or whooping-cough. These six deaths were equal to an annual rate of 0·9 per 1000, the zymotic death-rate during the same period being 1·9 in London and in Edinburgh. The 160 deaths in Dublin last week included 26 of infants under one year of age and 36 of persons aged upwards of 60 years; the deaths of infants showed a decline, while those of elderly persons were 13 more than the number recorded in the preceding week. Two inquest cases and one death from violence were registered; and the causes of nine, or nearly 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified: — Staff-Surgeon J. Bradley to the *Galatea*. Surgeons: J. A. Keogh to Hong-Kong Hospital; J. Mowat to the *Northampton* for the *Calliope;* and H. B. Hull to the *Vernon*, for the *Chasseur*.

ROYAL ARMY MEDICAL CORPS.

Captain H. W. Vaughan-Williams, attached to the 3rd Battalion Grenadier Guards in South Africa, is ordered home for duty.

INDIA AND THE INDIAN MEDICAL SERVICES.

Captain W. W. Webb (retired) is granted the temporary rank of Major whilst acting as Secretary to the Army Medical School at Netley.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion the Northumberland Fusiliers: Frederick William Wallace Whyte to be Surgeon-Lieutenant. 4th Volunteer Battalion the King's (Liverpool Regiment): Robert Fielding-Ould to be Surgeon-Lieutenant. 3rd Volunteer Battalion the East Surrey Regiment: Surgeon-Captain J. J. de Z. Marshall to be Surgeon-Major. 1st Bucks: Surgeon-Lieutenant F. J. Grindon to be Surgeon-Captain. 1st Volunteer Battalion the King's (Shropshire Light Infantry): Surgeon-Captain W. H. Packer to be Surgeon-Major. 3rd London: George William O'Flaherty Clark to be Surgeon-Lieutenant. 1st Volunteer Battalion the Gordon Highlanders: Surgeon-Lieutenant-Colonel P. B. Smith resigns his commission, with permission to retain his rank and to wear the uniform of the battalion on his retirement.

VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies: Surgeon-Captain W. Coates to be Surgeon-Major (in command) on increase of establishment.; Joseph Farrall Wright to be Surgeon-Lieutenant.

THE CRISIS IN CHINA.

At the time of our writing great anxiety most naturally exists as to the very serious state of affairs in China. It seems certain that the Taku forts, after having been bombarded by the warships of the Powers, have been captured, but it is not by any means clear what has become of the composite relief force which was despatched under the command of Admiral Seymour for the succour and protection of Europeans at Peking and elsewhere. We are all hoping to hear of its arrival at Peking or of its safety somewhere.

At the present time all the political interest of this country is focussed on the Foreign Office, War Office, and Admiralty, which must have their hands very full of work. It is extremely fortunate for all concerned that the enmity of the Chinese is of an indiscriminate character and directed against all foreigners alike, and that the Chinese forts fired upon the war ships of the international fleet without distinction, and, as a consequence, that the action taken had to be a conjoint one on the part of all the naval powers concerned. A large military force (of the native army mainly) is being sent from India to China. This will throw a great deal of work upon the medical services of that country and a large number of medical officers now serving in India will be required to embark with and accompany the troops ordered to China. The officers of both medical services have for a long time past found full occupation with the extra work they have been called upon to perform in connexion with plague, pestilence, famine, and war, which have filled pages in the mournful history of India of late years.

The following have been ordered to proceed with the force about to embark at Calcutta for service in China:—British field hospital, No. 22, Bombay. Native hospitals No. 39, Jalandhar; 42, Ambala; 43 and 44, Lucknow; and 47, Mhow. No. 4 field medical store depôt. Native general hospital of 200 beds from Calcutta. Lieutenant-Colonel Bookey, I.M.S., will be the principal medical officer.

TRANSVAAL WAR NOTES.

A military hospital capable of accommodating 500 invalids from South Africa is to be erected at Alton, Hants.

Lieutenant Martin, Lieutenant Scott, and Lieutenant Siberry, all of the R.A.M.C., are returning to England from South Africa invalided. Major Wills, Captain Erskine, and Lieutenant Morris, invalided, have arrived in England from South Africa.

The General of Communications at Cape Town reports the following officers discharged from hospital for duty for the week ending June 3rd:—Civil Surgeons Rook, Blackwood, Turton, and Roe.

The following steamships have arrived at Southampton and have brought invalids from South Africa who have been admitted to the Royal Victoria Hospital, Netley:—June 7th, the *Orient*, with six patients; June 10th, the *Orotava*, with 337 patients; June 15th, the *Simla*, with 268 patients; and June 18th, the *Custodian*, with 92 patients.

TRANSVAAL WAR CASUALTIES.

Civil Surgeon R. T. Fitzhugh died from enteric fever at the Imperial Yeomanry Hospital, Deelfontein, on June 15th.

Civil Surgeon E. Smith, attached to the R.A.M.C., died from enteric fever at the base hospital on June 16th.

Surgeon-Captain A. E. Vidler, Imperial Yeomanry, is reported missing.

Civil Surgeon H. D. Davies, attached to the Welsh Military Hospital, died at Springfontein on June 15th.

The death of Mr. Thomas Jones, F.R.C.S.Eng., chief of

the Welsh Military Hospital, is announced in a telegram from Springfontein.

We announced last week the death at Bloemfontein from enteric fever, on June 7th, of Civil Surgeon H. Bryant, attached to the Royal Army Medical Corps. Mr. Hugh Arnold Bryant, M.R.C.S. Eng., L.R.C.P. Lond., of Shaftesbury, was a son of Mr. Thomas Bryant, F.R.C.S., who, we know well, will receive the sincere sympathy of the profession in the great loss which he and his family have sustained.

The eightieth session of the Army Medical School, Netley, will terminate on June 30th. Owing to the war in South Africa there will be no public distribution of prizes.

Correspondence.

"Audi alteram partem."

THE METROPOLITAN HOSPITAL SUNDAY FUND.

To the Editors of THE LANCET.

SIRS,—The many appeals which have recently emanated from the Mansion House in respect either of the war or the famine in India are being so liberally and bountifully met that I gravely hesitate to make yet another call upon the never-failing generosity of the inhabitants of London. I feel sure, however, that in reminding the public that next Sunday is "Hospital Sunday," when for the twenty-eighth successive year collections will be made in every place of worship for the hospitals and dispensaries of this vast metropolis, they will admit that even the exigencies of the war should not divert them from rendering that annual help which has become so all-important a part of the incomes of the medical charities. While the war has drawn from the hospitals of London the ready services of medical men and nurses who have rendered devoted and invaluable aid in dealing with the sick and wounded at the front, it has materially prejudiced the institutions financially through the urgent competition of the multitude of appeals associated with the campaign.

But the progress of the war has effected no diminution of the numbers of sick poor for whom the hospitals of London labour unceasingly. Never was there a time in the history of the metropolis when there was greater need than now for the rendering of increased help towards the maintenance of these noble institutions, of whom some 200 owe their existence solely to the voluntary offerings of the benevolent public. When one reads that hundreds of beds are unused for want of funds and that last year the expenditure on the hospitals exceeded the income by nearly a quarter of a million sterling it seems time—even in a year of unparalleled stress and anxiety—to make a special effort in behalf of the medical charities of London. It is suggested that £100,000 might be raised this year for this object. Towards this Mr. George Herring has given £10,000 down and promised £10,000 more if £90,000 is raised. I trust that the generous public, by their contributions on Hospital Sunday will enable me to take advantage of this munificent offer.

I would add that, as usual, donations from those unable to attend a place of worship on Sunday may be sent to me at the Mansion House for addition to the Fund.

I am, Sirs, your obedient servant,

ALFRED J. NEWTON, Lord Mayor.

The Mansion House, London, June 19th, 1900.

À PROPOS DU RAPPORT DE LA COMMISSION DE "THE LANCET" SUR LA PULPE "VACCINALE" GLYCÉRINÉE.

To the Editors of THE LANCET.

MESSIEURS,—Je voulais répondre complétement au rapport de la Commission de THE LANCET chargée d'étudier la pureté de la pulpe vaccinale glycérinée du commerce; mais le Dr. Hime a éclairci plusieurs points dont je voulais m'occuper. Je me contenterai donc de traiter les côtés de la question non envisagés par mon confrère.

Qu'il me soit permis d'abord de faire une rectification bibliographique. Le rapport dit:—

To Copeman and to Chambon and St. Yves-Menard, working independently, apparently belongs the credit of determining that the addition of glycerine to vaccine lymph not only puts a stop to any multiplication of "extraneous" bacteria but actually in time kills non-spore-bearing organisms. ..... Independent testimony to this preservative and purifying action of glycerine has been offered by Leoni, Klein, Koch's German Commission, and other later observers, but little has been added to the results obtained by Copeman, working alone and with Blaxall, and by Chambon and St. Yves-Ménard working with Strauss."

Il y a là une grosse erreur. Le Professeur Leoni, alors directeur de l'Institut Vaccinal de l'Etat[1] à Rome, qui dans les lignes précédentes est désigné comme étant venu corroborer la découverte du Dr. Copeman d'une part et de MM. Strauss, Chambon, et St. Yves-Ménard, d'autre part, est précisément celui qui le premier a démontré la destruction des microbes se trouvant dans le vaccin par l'action de la glycérine, et a dit qu'au vieil adage, "Vaccin récent bon vaccin, vaccin vieux mauvais vaccin," il fallait substituer cet autre, "Vaccin récent mauvais vaccin, vaccin vieux bon vaccin."

Dans "The Milroy Lectures" publiées en 1898, que j'ai actuellement sous les yeux, le Dr. Copeman s'exprime ainsi: "In a paper presented to the International Congress of Hygiene held in London in 1891, and subsequently published in the Transactions of that Congress, I called attention to a special method for the bacteriological purification and preservation of vaccine lymph. This method consisted in the intimate admixture of a given amount of lymph, or rather vesicle pulp, with a sterilised 50 per cent. solution of chemically pure glycerine in distilled water, and in subsequent storage of the resultant emulsion in sealed capillary tubes for several weeks." Or les recherches du Professeur Leoni datent de 1889, et sa première publication sur ce sujet a été faite en 1890.[2]

Dans le travail presenté par Leoni au Congrès de Rome[3]—travail dont j'ai sous les yeux la traduction manuscrite, écrite de la main de Leoni lui-même—cet auteur dit: "En faisant des recherches sur les causes qui déterminaient les susdits accidents pathologiques signalés comme conséquences et complications des vaccinations, depuis l'an 1889 j'ai eu l'occasion de démontrer que ces accidents devaient être attribués à des micro-organismes pathogènes qui ordinairement contaminent le vaccin animal et en particulier le vaccin récent. ..... Les agents de la contamination s'épuisent dans le vaccin conservé pendant quelque temps dans la glycérine. Le vaccin conservé dans la glycérine pendant 1 à 4 mois après la récolte représente le type du vaccin pur, d'une virulence uniquement spécifique." Cette question de priorité a été portée devant l'Académie de Médecine de Paris par M. Hervieux, qui a proclamé que le Dr. Leoni avait avant tous autres découvert l'épuration de la pulpe vaccinale glycérinée par le vieillissement.

A la page 1235 de THE LANCET, 1re colonne, le rapport s'exprime comme suit:—

In one of the samples examined by us hairs of considerable length were found, which would indicate that the shaving had not been carried out sufficiently well in the first instance, and with shaving badly carried out thorough cleansing is impossible, the alternative interpretation of the presence of hairs being that they came from uncleansed portions of the animal and had—through inadvertence no doubt—been allowed to make their way into the pulp. The hairs in themselves are not harmful, but their presence indicates that certain precautions have not been taken.

La présence de poils dans la pulpe vaccinale n'indique pas que l'animal a été mal rasé; elle n'indique pas davantage que celui qui a récolté le vaccin ne s'est pas entouré de toutes les précautions nécessaires. La génisse la mieux rasée peut donner au préparateur de vaccin le plus soigneux une pulpe vaccinale remplie de poils. En effet, pendant les quatre,

[1] Cet institut a été supprimé depuis; le gouvernement italien estimant que l'institut de l'Etat nuisait aux instituts privés, et craignant en maintenant son institut d'arriver à voir disparaître ces établissements. L'avantage des instituts multiples se voit surtout lorsque se produit un affaiblissement momentané de la virulence vaccinale. Si dans une nation comme l'Angleterre par exemple il n'y avait qu'un institut d'Etat, et si pendant six mois—ce qui peut bien arriver—cet institut d'Etat ne récoltait que de la vaccine dépourvue de virulence (avec ou sans microbes) voici tout un pays privé des bienfaits de la vaccine pendant tout ce temps; tandis que s'il existe un certain nombre d'instituts, les particuliers ou l'Etat lui-même pourront en pareille occurrence recourir à les instituts. Or tous ceux qui s'occupent de la culture de la vaccine savent que, malgré toutes les précautions, il y a des moments où l'on n'obtient que du vaccin inefficace.

[2] Leoni: Revue d'Hygiène et de la Santé Publique, Août, 1890.

[3] Sur les Agents Spécifiques et Pathogènes du Vaccin, XIème Congrès International de Médecine, Rome, 1894.

cinq ou six jours que dure l'évolution des vésicules sur la génisse avant la récolte, les poils repoussent et quelquefois d'une façon très remarquable. Or la curette arrache une grande quantité de ces poils qui se trouvent ensuite dans la pulpe. Aucune précaution ne peut empêcher cela. Que l'on broie la pulpe avec le mortier, avec le broyeur du Dr. Chalybaüs ou avec n'importe quel autre instrument, les poils se retrouvent dans la pulpe préparée pour l'inoculation humaine.

Il y a cependant deux moyens d'enlever ces poils, celui qui consiste à les ôter un à un avec une pince; ce procédé est recommandé par le Professeur Layet[4] de Bordeaux. Il est peu pratique, car il demande un temps très long et pendant ce temps, malgré les précautions prises, les poussières de l'air peuvent tomber dans la pulpe et augmenter le nombre des microbes. Et parmi ces microbes il peut s'en trouver de nuisibles. Le second procédé consiste à tamiser la pulpe après trituration, sur un tamis métallique. C'est le procédé que j'emploie. La plus grande partie des poils reste sur le tamis, mais un certain nombre passent à travers et se retrouvent dans la pulpe. Beaucoup de tubes n'en contiennent pas, mais certains tubes peuvent en contenir plusieurs, très visibles, surtout si l'animal était de couleur foncée. Certains instituts, celui de Dresde par exemple, ne tamisent pas leur pulpe.

Je conclurai que tous ceux qui ont récolté ou vu récolter du vaccin savent qu'on recueille toujours des poils en même temps que la pulpe; que ces poils aseptisés autant que la couche épidermique constituant la pulpe vaccinale, ne présentent aucun inconvénient; que lorsqu'on récolte une très petite quantité de vaccin il est facile avec une pince stérilisée de retirer tous ou presque tous les poils; mais que lorsqu'on prépare de grandes quantités de pulpe la seule chose possible est de la tamiser après le broyage—le tamisage n'enlevant pas tous les poils—enfin qu'il serait plutôt nuisible d'exposer la pulpe vaccinale aux poussières de l'air pendant le long temps nécessaire pour débarrasser le vaccin de tous les poils. J'ajouterai enfin que j'ai en main quelques tubes provenant de l'Académie de Médecine de Paris, et que tous contiennent des poils.

A la page 1236, 1re colonne, le rapport dit:—

The presence of a small quantity of blood, therefore, is not considered to be of any importance except, as we have pointed out, that it indicates that perhaps more care might have been taken in the collection of the sample. It may, however, be pointed out that it has been proved by recent experiments that the presence of blood, even in small quantities, in vaccine lymph exerts a marked deteriorating influence. The lymph rapidly loses some of its potency, the activity falls more rapidly, and extraneous organisms develop more readily than in lymph so collected that it is not tinged with blood.

On emploie deux procédés, dans les instituts vaccinaux, pour la récolte de la pulpe. Le premier consiste à saisir la peau, au dessous de chaque pustule à l'aide d'une pince hémostatique et à gratter la pustule avec un instrument quelconque. Ce procédé ne donne que peu de sang et avec un bon outillage, avec des pinces de formes différentes, on peut avoir une pulpe complétement blanche. Mais il faut beaucoup de temps, et pendant ce temps le champ vaccinal préalablement aseptisé reçoit des poussières. On sait en chirurgie abdominale qu'une opération a d'autant plus de chances de donner un résultat favorable qu'elle a duré moins longtemps. Il en est de même pour la récolte du vaccin; la pulpe a d'autant moins de chance d'être souillée par les microbes de l'air que la durée du grattage est plus courte.

Dans le second procédé on gratte directement avec la curette. Il y a alors nécessairement du sang; plus ou moins suivant les animaux; suivant que la peau est plus ou moins congestionnée[5]; mais il y a toujours du sang si la récolte se fait sur l'animal vivant. A Cologne[6] la récolte se fait après la mort de l'animal, il n'y a pas de sang dans la pulpe par conséquent. On peut obtenir cependant du vaccin complétement blanc avec la curette sur l'animal vivant en grattant très vite et en ne revenant pas deux fois au même endroit; mais alors, ou bien on ne récolte ainsi qu'une partie du vaccin, le reste étant nécessairement mélangé de sang; ou bien on a une perte considérable. En résumé la curette permet d'aller très vite, ce qui, en dehors de l'économie de temps, évite en grande partie les souillures par les microbes de l'air; mais avec la curette on obtient le plus souvent un vaccin rosé ou rouge; c'est à dire un vaccin contenant du sang.

[4] Layet: Traité Pratique de la Vaccination Animale, Paris, 1889.

[5] Lorsque la peau est très congestionnée le vaccin est généralement moins virulent.

[6] Report to the Local Government Board on the preparation and storage of glycerinated calf vaccine lymph, with an introduction by the medical officer. London, 1897; p. 14.

Je dois dire ici que la grande majorité des instituts vaccinaux[7] récoltent avec la curette sur l'animal vivant sans se préoccuper de la présence du sang. J'ai pu m'en rendre compte dans les visites faites par moi à un grand nombre d'instituts vaccinaux en France et à l'étranger.

Le rapport prétend que le sang, même en petite quantité, exerce une action nuisible très manifeste sur le vaccin et lui fait perdre rapidement ses propriétés et que les microbes étrangers s'y développent plus volontiers. Je m'inscris absolument en faux contre cette assertion. La virulence se conserve aussi bien—je n'ose pas dire mieux—j'en ai plusieurs fois fait l'expérience, dans le vaccin contenant du sang que dans celui n'en contenant pas, et le nombre des colonies se développant après ensemencement n'est pas plus élevé. Mais pour faire l'expérience il ne faut pas comparer un vaccin quelconque ne contenant pas de sang avec un autre en contenant; l'un peut être vieux et l'autre jeune; l'un peut être concentré et l'autre dilué. Il faut comparer deux vaccins de semblable dilution provenant du même animal; c'est ce que j'ai fait.

Le Dr. Hime a dit que les expériences de la Commission ne prouvaient rien au point de vue scientifique; c'est un peu vrai. On a pris sur le marché différentes marques, sans s'inquiéter de l'âge du vaccin, sans s'inquiéter de son degré de dilution, et on a tiré des conclusions de l'examen de les vaccins. Le rapport dit, p. 1235:—

If the vaccine lymph has been carefully collected and glycerine has been allowed to act for a month the number of organisms growing in any of these media should be small. If the number growing is very large, that is, if it runs up to anything like 500 in the vaccine for a single inoculation, we suggest that the maker should be apprised of the fact that the glycerination is not being properly carried out and that any stock of lymph should be returned.

La dilution de la pulpe est variable suivant les instituts; les uns mettent: pulpe 1, glycérine 1; d'autres pulpe 1, glycérine 2; d'autres pulpe 1, glycérine ou eau glycérinée 4; d'autres pulpe 1, eau glycérinée 14 (Berlin)[8]; d'autres enfin pulpe 1, eau glycérinée 15 (Cologne).[9] Si on ensemence des boîtes de Petri avec la dilution à 1 pour 1, il naîtra nécessairement 15 fois plus de colonies que si on les ensemence avec la dilution à 1 pour 15. Si par exemple la première donne 500 colonies, la seconde donnera 15 fois moins ou $\frac{500}{15} = 33$ colonies environ. Or d'après le raisonnement de l'auteur du rapport de THE LANCET le premier tube serait mauvais et le second excellent; tandis que si les deux dilutions ont été faites avec une pulpe de virulence moyenne la première peut être très bonne et la seconde médiocre au point de vue des résultats cliniques. Je m'appuie pour dire cela sur des expériences personnelles publiées dans *La Gazette Médicale du Centre*. Dans les pulpes examinées par la Commission de THE LANCET, il y en a de dilutions très différentes, et il n'a pas été tenu compte de les différences. De même la Commission aurait pu s'enquérir de l'âge du vaccin qu'elle étudiait, cela aurait donné plus de valeur à ses études. La Commission aurait pu aussi—elle aurait dû même—si elle voulait établir une classification des vaccins d'après leur pauvreté en microbes, tenir compte de tous ses examens sur les vaccins de chaque provenance; elle n'aurait pas ainsi classé en tête une marque de vaccin, qui dans un examen antérieur présentait tellement de microbes qu'ils étaient incomptables. Il est vrai de dire que ce vaccin à microbes incomptables était peut-être excellent au point de vue de la virulence. Mais la Commission a négligé d'étudier la valeur réelle du vaccin.

Un autre point négligé par la Commission, c'est la présence dans les pulpes examinées des microbes spécifiques du vaccin, car, il faut bien le dire, s'il y a dans le vaccin des microbes indifférents ou nuisibles, il y en a aussi d'utiles; et tous les auteurs qui se sont occupés de cette question des microbes du vaccin savent qu'Antony a démontré qu'en ajoutant certains staphylocoques (micrococque porcelaine) à de la pulpe vaccinale on augmente sa virulence, tandis qu'on la diminue en ajoutant d'autres microbes, notamment certains bacilles. Le staphylocoque utile, d'après M. Antony[10] "donne naissance, sur agar, à des colonies aplaties, crémeuses, d'un blanc de porcelaine éclatant, tout à fait caractéristique,

[7] Voici ce qui se passe à Dresde: "The pulp is collected by scraping with a Wolkmann's spoon, but as Dr. Chalybäus goes over the same surface again and again a not inconsiderable amount of blood becomes mixed with the epithelial scrapings." (Report to the Local Government Board, &c., p. 12) A l'Académie de Médecine de Paris le vaccin contient du sang, comme le prouve sa couleur rouge.

pouvant atteindre un centimètre de diamètre, lorsqu'elles sont peu nombreuses et bien isolées. Sur gélatine ce coccus pousse lentement, les colonies n'apparaissent qu'au bout de 5 à 8 jours; la liquéfaction du milieu nutritif est trés lente et ne se produit parfois qu'après 15 jours de culture. Ce microcoque existe dans le vaccin vivant d'une façon constante." "Le microcoque porcelaine ne se rencontre pas sur l'animal avant la vaccination (Antony).[11] Il ne s'y rencontre pas avant qu'on ait pratiqué les inoculations. Il semble provenir *du vaccin uniquement;* car sauf le cas de pulpes glycérinées très anciennes, il se rencontre constamment dans cette matière virulente." "Au point de vue bactériologique un vaccin peut être réputé de qualité irréprochable lorsqu'on n'y trouve, après frottis de la pulpe sur un tube d'agar, que des colonies de coccus porcelaine." "Les principales espèces microbiennes étrangères qu'on y rencontre sont le *staphylocoque jaune*, qui s'y trouve en proportion le plus souvent infinie; la persistance de celui-ci en trop nombreuses colonies doit faire suspecter le vaccin conservé; quelques micro-organismes d'impureté (saprophytes) vulgaires, tels que le bacillus subtilis, le bacille de la pomme de terre, &c. Ces derniers produits si répandus dans les étables, existent dans le vaccin en faible proportion. Leur présence ne semble avoir aucune action défavorable sur l'évolution vaccinale (Antony)."

D'après les recherches d'Antony un seul microbe, parmi ceux qu'on trouve d'ordinaire, pouvait être nuisible, lorsqu'il existe en trop grande quantité; le staphylocoque jaune. D'après mon expérience personnelle ce sont les vaccins les plus riches en staphylocoques jaunes qui produisent sur l'enfant les vaccins suintant, empesant le linge et se couvrant de croûtes irrégulières, et la vaccine ulcéreuse. D'autres microbes nuisibles, pathogènes, peuvent aussi se rencontrer accidentellement. Aussi eut-il été plus utile de rechercher quelles étaient les bactéries contenues dans le vaccin, que de les compter: *non numeranda, sed ponderanda.*

J'ai dit qu'il y avait des microbes utiles dans le vaccin, je veux revenir sur cette question. Si Antony a augmenté la virulence du vaccin en ajoutant des micrococques porcelaines, Maljean[12] a été plus loin; il a obtenu sur les animaux des vésicules vaccinales en inoculant des cultures de ce microbe. Mon savant ami Boureau[13] et moi dans un certain nombre d'expériences avons obtenu des vésicules vaccinales, 1° en inoculant à des génisses tous les microbes du vaccin réunis; 2° en inoculant les micrococques porcelaines; et nous n'avons rien obtenu en inoculant isolément ou réunis les microbes autres que le micrococque porcelaine. Ce qui prouve une fois de plus que sans ce microbe il n'y a pas de vésicule vaccinale.

Un certain nombre d'auteurs avaient déjà avant Maljean obtenu les vésicules caractéristiques en inoculant des cultures de vaccin. Je citerai Quist[14] en 1883; Voigt[15] en 1885; Carmichael en 1887; Garré[16] en 1887; Grigorien en 1889; Voiton en 1890; Ruete[17] en 1891 et en 1893; Buttersack[18] en 1894; Martin et Ernst en 1895. J'ajouterai que le Dr. Copeman[19] avec le Dr. Blaxall ont eux-mêmes isolé un microbe, qui inoculé aux génisses donne des vésicules vaccinales typiques.

On m'objectera que des pulpes glycérinées vieillies, ne contenant plus de microbes, produisent par l'inoculation des vésicules vaccinales aussi bien que des pulpes fraiches, riches en microbes. A celui je répondrai que les pulpes très vieilles ne produisent que des résultats nuls ou incomplets; que presque toujours dans les pulpes qui restent actives on trouve des microbes et surtout le microcoque porcelaine; mais que, même si on n'arrivait pas à cultiver ce microbe sur les milieux de culture ordinaires cela ne prouverait pas son absence, mais simplement que l'influence de la glycérine et du temps l'a rendu inapte à se cultiver sur les milieux ordinaires, et que pour le cultiver il faut le faire passer à nouveau par l'animal vivant. De même certains produits, liquides ou solides, dans lesquels on ne peut déceler le bacille de la tuberculose, donnent naissance à la tuberculose lorsqu'on les inocule au cobaye.

Le Dr. Hime a insisté avec raison sur ce point que la virulence de la pulpe vaccinale a une plus grande importance que le nombre des microbes. Ce que l'on doit demander au vaccin c'est avant tout qu'il préserve de la variole. Du vaccin trop épuré peut ne produire aucune vésicule et exposer les personnes inoculées à une fausse sécurité. Si l'on inocule un enfant pour la première fois et si l'on n'obtient aucun résultat, on peut recommencer la vaccination jusqu'à ce qu'on ait obtenu des vésicules; mais si l'on revaccine un adolescent ou un adulte déjà inoculé, et si le vaccin ne réussit pas, on sera très porté à admettre que le sujet subit encore l'influence de l'inoculation antérieure; surtout si le même vaccin a donné des résultats chez l'enfant. Mais ce qui prouve que cet adulte resterait exposé à contracter la variole, c'est que si on le vaccine avec une pulpe fraiche très virulente l'inoculation produira des vésicules.

Je résume ma manière de voir en disant: dans les instituts vaccinaux l'inoculation des génisses, la récolte et la préparation du vaccin doivent être conduites avec l'asepsie la plus complète, les différentes opérations devront se faire dans le plus court espace de temps possible pour éviter les contaminations par les germes de l'air. Les étables devront être lavées très fréquemment avec des liquides antiseptiques[20] ou désinfectées avec des vapeurs de formol. Chaque récolte de pulpe vaccinale, après avoir été glycérinée, devra être soumise à l'examen bactériologique, mais bien plutôt pour déterminer les espèces microbiennes qu'elle contient que pour compter les colonies qu'elle peut produire.[21] Si cette pulpe contient des microbes nettement pathogènes comme le streptocoque de l'érysipèle, elle devra être détruite; si elle contient un grand nombre de staphylocoques jaunes elle ne devra être employée qu'après vieillissement et après s'être assuré cliniquement qu'elle produit de la vaccine normale et qu'elle a conservé une grande virulence.

L'essai clinique devra être considéré comme plus important encore que l'examen bactériologique, car seul il montre le degré de virulence du vaccin et la tendance des vésicules à donner des croûtes irrégulières et de la vaccine ulcéreuse. On ne devra employer qu'un vaccin d'une virulence parfaite.[22] Pour les inoculations d'enfants et en dehors des épidémies de variole on pourra préférer la pulpe vieillie donnant lieu à une aréole moins étendue et à une réaction inflammatoire moins grande; mais pour les revaccinations et surtout en temps d'épidémie il est indispensable d'employer une pulpe jeune très virulente, capable de donner presque autant de résultats pour les revaccinations que pour les vaccinations.

J'ajouterai qu'il est une chose qui pour moi n'est pas démontrée, à savoir qu'un vaccin peu virulent—ancien ou récent—donnant des vésicules peu nombreuses et peu développées protége autant de la variole qu'un vaccin récent très virulent, donnant des vésicules très développées à chaque inoculation, et produisant sur une inoculation par coupure dès le troisième jour une vésicule unique de la longueur de la coupure et à bords rectilignes.

Enfin pour terminer je ferai part à la Commission de THE LANCET d'une opinion devant peser d'un certain poids en la matière et se trouvant absolument en désaccord avec les idées émises par le rapporteur: je veux parler de l'opinion de l'Académie de Médecine de Paris. Je transcris ci-dessous la notice qui accompagne chaque envoi de tubes par l'Académie de Médecine.

"*Avis très important.* (*Le vaccin de génisse se conserve difficilement.*) Prière d'employer le vaccin en pulpe dans les dix jours qui suivent la réception, pour éviter les insuccès et l'altération possible de la pulpe, altération qui pourrait occasionner des accidents septicémiques."

[21] Toutes les récoltes de l'Institut Vaccinal de Tours sont soumises à l'analyse bactériologique par le Docteur Boureau, et ne sont utilisées qu'après cet examen et après l'épreuve clinique.

[22] Sur près de cent mille tubes faits chaque année à l'Institut Vaccinal de Tours, il n'y a pas plus d'une dizaine de tubes qui produisent pour des causes diverses des résultats nuls ou incomplets.

THE RELATIONSHIP OF MALARIA AND THE MOSQUITO.

To the Editors of THE LANCET.

SIRS,—I may have been reading papers recently, both medical and lay, incorrectly, but I have gathered from them one and all that the unequivocal dictum of those who have been investigating the etiology and prophylaxis of malaria is to the effect that (1) the mosquito is the alternative host with man of the malaria parasite; (2) that malaria is conveyed to man by the mosquito and in no other way; and that (3) as a logical consequence it is only necessary to take precautionary measures against the malaria-bearing mosquito to be rid of malaria. In the *British Medical Journal* of Feb. 10th Professor Grassi is reported to have given it definitely as his opinion, "No man, no malaria; *no mosquito, no malaria*"; and Professor Celli and other investigators appear to be of the same mind. In THE LANCET of May 12th (p. 1400) Major Ronald Ross, I.M.S., writes: "The mosquito theory scarcely stands in much need of further proof; it was established long ago. We already know that malarial fever is communicated by gnats." Dr. Patrick Manson in a lecture reported in THE LANCET of May 19th, p. 1419, also says: "..... There cannot be the slightest doubt that the mosquito acts the part of transmitting agent as well as definitive host of the malaria parasite." In the Report of the Malaria Expedition of the Liverpool School of Tropical Medicine are these lines:—

> To sum up, although some points of importance still require investigation it has been shown that certain species ot gnats are definite hosts of the hæmamœbidæ; that the parasites are conveyed from diseased to healthy vertebrates (intermediary hosts) by these insects; and that the definitive hosts of the human parasites are certain species of anopheles.

There seems to be such unanimity of opinion on the subject in the minds of these investigators that pamphlets have been issued with instructions to those inhabiting malarious districts as to the best methods of diagnosing the malaria-bearing species of mosquito, for capturing it and destroying its larvæ in more wholesale fashion and for avoiding its bite (would that it were possible!). These are the only precautions recommended. Nothing is said as to telluric, paludal, or atmospheric conditions except as they relate to the mosquito. It is the mosquito or nothing—*aut anopheles aut nullus*. That mosquitoes may frequently act as alternative or intermediary hosts with man of the malaria parasite seems now a well-established fact, but this is a widely different theory to the hard-and-fast doctrine that a species of "anopheles" is solely responsible for all malarial fevers in mankind. It is to this last dogma that I demur. The problem of malarial infection appears to me to be far too complex for so simple a solution and the question being of such great importance it is desirable to be fully satisfied with the new creed before abandoning the old.

As a sometime resident in different parts of South America, a country where neither malaria nor mosquitoes are entirely unknown, and as a native of the Fens where ague, twin brother of malaria, was common until a few decades ago, I find it difficult to believe that malaria is *only* acquired from a certain species of mosquito and that all telluric and atmospheric conditions are factors that may be safely disregarded. That I am not entirely alone in my doubts may be seen by reference to medical works of recent date, such as "Health Abroad," edited by Dr. E. Hobhouse, where other causes, such as a chill, a wetting, the turning over of virgin soil, exposure and fatigue in malarious districts, are credited with causing fever as well as direct infection from mosquitoes. Also in the *Times* of May 28th in an article "From the Vaal River to Pretoria" the writer speaks of Pretoria thus: "Its heavy drawback, indeed, is its periodical insalubrity. Whether owing to minute malaria in the soil, or to the unmentionable filthy habits of the genuine Boer, Pretoria is liable to epidemics of deadly jungle fever, as I learned to my bitter cost. The miasmas at sunset, attended by a bone-piercing cold, are especially dangerous." But it is now implied that the "miasma" is an obsolete myth. When I was in British Guiana the houses of sugar-planters and overseers were always built upon piles or pillars to raise the living rooms some 10 or 12 feet above the miasma which was supposed to rise after sunset and to be particularly dangerous as pregnant with the malaria poison. Most travellers in malarious districts prefer to sleep when camping out raised some distance above the ground and generally sling their hammocks so, while in the navy landing parties are instructed to make elevated platforms with boughs on which to sleep and are supplied with small axes for the purpose. Kingsley, in "Westward Ho," describes how immunity from fever was obtained when the men slept beyond the reach of the miasma. We are now told that the real reason of the danger of sleeping on or near the ground is that the mosquito is a low flyer and a night feeder. "The mosquito," it is said, "does not mount high in the air." My own personal and very painful experience does not confirm this statement. Mosquitoes were my constant companions to whatever height above the ground I ascended and were as unremitting in their attentions upon the first-floor as upon the ground floor and by day as well as by night. They may be observed upon ceilings, rafters, and roofs, and on the leaves of trees as well as near or on the earth or water. But it is solely upon this assertion that a popular and universal belief some centuries old is discredited and the mosquito theory brought in triumphant as amply explaining the miasma.

Then, again, in the same colony there was a very general and well-founded belief that young men freshly arrived from the temperate climates, although they would be bitten more voraciously than the older residents, yet were not very liable to malarial fever until they had resided about a year in the country. Yet on the mosquito theory one would think that these fresh arrivals bitten from head to foot and living amongst men constantly down with fever, would become infected within a week of their arrival on a plantation.

To break fresh earth and turn up virgin soil has long been known to be a prolific cause of malarial outbreaks. The workmen and soldiers employed by the French in road-making during their Madagascar campaign succumbed in large numbers to malaria. It was the same with the workmen on the Panama Canal and Colon Railway where every "sleeper" was said to have cost a life. The mortality from malarial fever during the construction of the Colombo and Candy Railway was also exceptionally high. But these facts, we are now informed, are explained by the formation of little pools and puddles as the workmen dig, in which "anopheles" lays its larvæ (*vide* p. 30 of the Report of the Malaria Expedition). "Faith," as Mark Twain's schoolboy said, "is believing what you know ain't so." In 1865 at Hong-Kong the 11th Regiment stationed there and engaged on guard duty while the Kairoon docks were being made suffered from a severe outbreak of malarial fever which was attributed to the turning up of the earth. Other troops stationed there while the new Murray barracks were being constructed were also the victims of a virulent epidemic of malaria. Deaths were so numerous that salutes ceased to be fired and bells to be tolled so depressing were they in their frequency. Also in the same place in 1891, 1892, and 1893 the Royal Engineers were engaged in excavations at the depth of from 12 to 15 feet for the emplacement of heavy guns and while engaged in this work were constantly the victims of malaria. At the time the turning up of the earth was considered to be the invariable cause of the epidemics; and it is a noteworthy fact in the last instance that the Argyll and Sutherland Highlanders also stationed there at the same time, who were not engaged in the excavation works, did not suffer similarly but enjoyed a comparative immunity. Moreover, the soil was a kind of decomposed granite, almost like sand. "*After heavy rain no water remained.*" I quote the words of my informant, an officer of the Engineers engaged on these works at the time.

It is very difficult in the face of facts like these and without further evidence to accept the "anopheles" theory and to discard telluric and atmospheric agencies. It is hard to believe that the mosquitoes would make a differential diagnosis between the Engineers and the Highlanders. Moreover, Hong-Kong is not a place particularly infested with mosquitoes. In the Ashanti expedition in 1873–74, in an area between Cape Coast Castle, Elmina, and Accra to Kumassi, about 120 miles inland, there was, I am informed by an officer who accompanied the expedition, "any amount of malarial fever but practically no mosquitoes," although in the regions to the right and left of this district mosquitoes abounded. The *Simoon* was the hospital ship to this expedition. Those who were first sent on board her derived much benefit, but in rather less than three months both the naval and the military officers condemned her and declared that malarial fever was endemic on board. Wounded men without fever would get fever from going on board. The *Simoon* was therefore sent away and the *Victor*

Emmanuel replaced her, but in this ship the same effects were not observed. If mosquitoes were the means of conveying infection in the first vessel from the fever-stricken to the free, why were they not also in the second?

That the whole question bristles with difficulties is exemplified, I think, by the following episode related to me by a naval officer who accompanied the expedition and subsequently commanded it. In the spring of 1876 a punitive expedition was sent up the Niger from H.M.S. *Active*. The party ascended the river in a steamer somewhat larger than an ordinary Dover and Calais boat. The expedition was away between six and eight weeks. There were a few mosquitoes, but they did not trouble much. Quinine and spirit were served out every morning and the men were particularly well fed and cared for, always sleeping under cover and rarely being ashore more than three or four hours at a time. There was practically no sick list except of the wounded and the men were very fit and well from first to last. The men returned to the *Active*. She steamed out to sea and within a week afterwards nearly all of those who had taken part in the expedition were down with fever of a severe type. About six died and many were invalided home. Yet the fever did not break out during the many weeks that the expeditionary force was up the river, but only afterwards when the ship was cruising about at sea and when improved conditions prevailed. Nor was the morning dose of quinine discontinued when these men returned to their ship. Quinine was regularly served out daily to the entire ship's company all the time the vessel was on the West Coast. Are we to believe that "anopheles" was directly responsible for this outbreak or for its spread if a single case had developed? Assuming, for the sake of argument, that there were mosquitoes on board and that they became infected from feeding on one or two cases and so infected others, still this would not explain why only the men of the expeditionary force were attacked and why the rest of the crew remained free, which was the case.

And what are we to say of the etiology of ague in the Fen districts of this country? Was that also conveyed to man only by gnat-bites? The gnats remain still in some numbers but ague has disappeared. The past generation suffered much from it. Tertian and quartan ague were then endemic in many districts, but with the better drainage of the Fens, with the dykes, pumps, and syphons of later years, it has gone for ever, as in many other parts of Europe. Is it at present so absolutely certain, as Professor Grassi maintains, that the malaria parasite cannot exist in some phase or other of its life's cycle in the soil or in water?

In many tropical regions malaria is most rife whenever heavy rains succeed a spell of dry weather or wherever rank vegetation is decomposing. And in newly taken up countries, such as Mashonaland and Rhodesia, as the long coarse grass gets eaten down and improved by stock malaria tends to be less prevalent. That these conditions are of importance solely because they affect the multiplication or diminution of a certain species of mosquito seems somewhat difficult of belief.

Up the river Parana in South America mosquitoes teem in their millions and billions and probably every branch of the family is there strongly represented—"anopheles," "culex," and all their near and distant relations. Sporadic cases of malaria, or "chuchu," as the natives call it, are not unknown, and in Tucuman, a province somewhat west of the main river, malaria is common—owing, Dr. G. H. Pennell thinks, to its being a large sugar-producing district *where the soil is much disturbed* in its cultivation. Yet the countries adjacent to the Parana are not malarious, although hundreds of square miles of swamp and forest line its banks and those of its innumerable tributaries. Paraguay, Entre Rios, and Uruguay are extremely healthy. Moreover, people in these countries are great travellers and on this account it is inconceivable to me, if the mosquito theory is a sound one, why the entire Parana region is not as fever-stricken as any on earth. As a logical sequence it should be. Mosquitoes are there, every tribe of them, and just an occasional case of malaria to initiate a devastating epidemic. Yet no region in the world is much healthier!

The fact that an off shore wind from a malarious coast will sometimes induce an outbreak of malarial fever amongst the crews of ships lying out in estuaries or even passing some 50 miles from land seems to prove conclusively that the atmosphere has some intimate connexion with the disease even if malaria is not airborne. The argument that such ships probably harbour mosquitoes which are the real cause of the outbreak hardly holds good because it is only the *land* breeze which does the mischief, and it is difficult to understand why the land breeze should suddenly stimulate "anopheles" to activity any more than a wind from another direction; whereas on the assumption that malarial fevers are intimately related in some way or another with paludal, miasmatic, telluric, or atmospheric conditions this fact is intelligible enough. This latter view is still held in the navy, for it is customary at certain times of the year in ships on the West Indian station for the petty officers to go round at night and see that the awnings are up to protect the men sleeping on deck from the land breeze and to prevent them throwing off their coverings as they feel tempted to do on sultry nights. If the mosquito theory is to hold sway this duty is evidently a work of supererogation and a farce.

When one considers the phases in the life-history of some of the larger organisms, such as the frog and butterfly, to mention no others, it seems conceivable that the hæmoplasmodium malariæ of man found also in "anopheles" may still exist elsewhere under some other form as yet unrecognised.

> There are more things in heaven and earth, Horatio,
> Than are dreamt of in our philosophy.

The only theory to my mind that at all fits the case in some of its bearings is that in certain regions of the earth the parasite of malaria, by whatever name it may be called, disguised under whatever form, or in whatever phase of its existence, is endemic and ubiquitous, just as the tubercle bacillus is in other parts, and either readily finds a habitat in the human body and there lies dormant or is prepared constantly for invasion if occasion offers. (That the parasite can remain quiescent within the body is evidenced by the long intervening periods that sometimes elapse between attacks of fever, often of many years.) We know that this is the case with many micro-organisms and that each of us carries, so to speak, a "viper in his bosom" in the shape of various bacteria, harmless so long as we keep in health, but ready to turn and injure us whenever they can overpower the protective phagocytes, the constabulary of our tissues.

I do not, however, venture to propound any theory of my own, but I would suggest from some of the foregoing considerations that the case for the mosquito being in all instances the direct and sole agent in the production and transmission of malaria has not been satisfactorily made out as yet and that it behoves us for awhile to suspend our judgment and not to abandon the precautions against malaria that the accumulated experience of generations and the dictates of common-sense have taught us in favour of one line of prophylactic treatment only, to say nothing of its feasibility—i.e., that of dealing with the mosquito. Another source of malarial infection has certainly been discovered, thanks to the untiring researches of the workers in this field, but that it is the only source of infection needs yet, I think, some further proof.

I am, Sirs, yours faithfully,

Charles-street, W., June 5th, 1900. J. H. DAUBER.

MONOGAMY IN ITS RELATION TO LONGEVITY AND THE DISEASES OF LATE LIFE.

To the Editors of THE LANCET.

SIRS,—In his interesting article on this subject in THE LANCET of June 9th Dr. Campbell seems to neglect the importance of longevity to the human race as a whole and to ignore the fact that death and renewal of individuals is of vast importance in the existence and advance of any race of beings. I question whether Nature's law is a tendency to death "soon after the cessation of reproductive life," but rather "as soon as the individual has ceased to be of use to the race." If the former were the law bees and other practically neuter beings could not exist, and it is difficult to see how women could be as long (or even longer) lived as men, for that they should inherit the length of years of their fathers, and so defeat the law, does not seem a satisfactory explanation. On the other hand, it is difficult to exaggerate the importance of woman's post-reproductive life to the race in the past and amongst the less civilised at the present day. During these years she provided food and raiment, nursed the sick not only administering but also preparing her various remedies, and by her skill and knowledge

was of more immediate importance to the well-being of the race than her youthful sister. Modern civilisation and invention have destroyed her usefulness, and it is possible, but scarcely probable, that the increase of carcinoma, which especially attacks women during these years, is Nature's first effort to remove these useless individuals!

Let me hasten to add, with Dr. Campbell, that I do not advocate any startling measure of reform for the employment of women, but if women in their youth could be taught some useful employment, they might spend these years to their own good and to the advantage of the race. His suggestion of a selection of parents has often been discussed before, and is a fascinating idea, but we have not, and probably never shall have, either the power or the skill to carry it out.

I am, Sirs, yours faithfully,

Ottery St. Mary, June 15th, 1900. CLAYTON JONES.

"THE RELATIVE VALUE OF SYMPTOMS IN ACUTE PERITONITIS."

To the Editors of THE LANCET.

SIRS,—I value very highly Mr. Mansell Moullin's appreciation of my article on "The Relative Value of Symptoms in Acute Peritonitis" and regret that he cannot agree with my main contention as to the necessary presence of true rigidity of the abdominal walls in that condition. May I point out that the position stated in my paper does not depend upon the three cases mentioned therein, these being only given as more or less typical, but upon more than 20 years' careful examination of hundreds of cases. On the other hand, Mr. Mansell Moullin brings forward one case which was not, so far as his communication goes, proved by post-mortem examination. This case was, he says, septic and may well have been one of septic intoxication or septic poisoning, in which the initial or repeated doses of poison totally preclude from the first all reactive or protective efforts on the part of the peritoneum, which I conceive are the essence of peritonitis. Peritonitis in these cases never occurs; it has never any chance of existence.

Mr. Mansell Moullin mentions abdominal cramp as a close imitation of the characteristic rigidity of acute peritonitis, and I quite admit this, but such cramp is, after all, only an imitation fairly easily detected, and one which, I am sure, would never deceive Mr. Mansell Moullin or any other abdominal surgeon whose sense of touch and whose patience were fully trained.

I confess that I cannot agree with, or even admire, the ingenuity of the logic which declares that our diagnosis will be the more reliable in proportion as we realise the total unreliability of the factors which constitute it. But, after all, this is a principle which can neither be proved nor disproved by the mere *ipse dixit* of any one man. If my surgical and gynæcological *confrères* would look for and record the presence or absence of this symptom in each case the question would soon be settled. In the meantime I can confidently recommend the test, whatever may be thought of the explanation, which I have ventured to propound.

I am, Sirs, yours faithfully,

Manchester, June 18th, 1900. E. STANMORE BISHOP.

To the Editors of THE LANCET.

SIRS,—Many will agree with Mr. Mansell Moullin that Mr. Stanmore Bishop's rigidity of the abdominal walls is not absolutely diagnostic of peritonitis and also is not essential; that a marked rigidity may be found in such cases as gastric ulcer or hysteria without peritonitis; and that rigidity may not be present during the first stage of shock in perforative peritonitis nor even at all during some cases of peritonitis due to perforation in typhoid fever.

Mr. Bishop omits in his catalogue the more important fact mentioned in Mr. Treves's graphic description, "abdominal respiration ceases." This is invariable even when rigidity is absent; if general peritonitis exists the whole abdomen is motionless during respiration except that a slight reversed motion may be caused in the upper part by dragging in of the abdominal wall by the exaggerated thoracic movement in inspiration. Abdominal respiration is not abolished by any of the colics or intestinal pains and its absence seems therefore a better sign to rely on than rigidity.

I am, Sirs, yours faithfully,

Brighton, June 18th. WALTER BROADBENT.

HORSE AMBULANCES.

To the Editors of THE LANCET.

SIRS,—The subject of the provision of a horse ambulance in towns having been raised in a recent issue of THE LANCET, may I relate to you what has been done in this direction in Oxford, which, so far as I know, is the only place where facilities of this kind are available? About 20 years ago a private subscription was got up and a horse ambulance purchased. It has been kept at one of the livery stables which has the advantage of a telephonic service and is thus in connexion with the hospitals and with the Acland Nursing Home. Anyone can have the use of it for about an ordinary cab-fare. Three years ago, the first ambulance having become somewhat worn out, a second horse ambulance was obtained, also by private subscription, and is in constant use. A nurse and medical man can travel with it when necessary. It is also used for local military purposes in connexion with the Oxfordshire Yeomanry.

I am, Sirs, yours faithfully,

Oxford, June 19th, 1900. HORATIO P. SYMONDS.

To the Editors of THE LANCET.

SIRS,—I notice that the subject of public ambulances has been mentioned more than once in THE LANCET recently. May I be permitted to point out to you that we have had such a one in Oldham for about two years or more. It was presented to the town, is kept at the fire-station, horsed by the fire brigade horses, and worked by the firemen, all of whom hold St. John Ambulance certificates. It turns out within one minute of receiving a call. One evening during the severe weather last winter in a blinding snowstorm there were no less than five calls for its services.

I am, Sirs, yours faithfully,

Oldham, June 20th, 1900. EDWARD KERSHAW.

PLAGUE IN AUSTRALIA.

(FROM A SPECIAL CORRESPONDENT.)

THE returns of plague in Sydney for the week ending May 5th are as follows: remaining at the beginning of the week, 75; admitted, 38; died, 10; discharged, 4; remaining at the end of the week, 99. The total cases are now 193 and the total deaths are 63; the number discharged recovered is 31. Total "contacts," 1130; "contacts" remaining, 235; cases among "contacts," 7. It is doubtless understood that the "cases among contacts" are those of persons who fell ill at the isolation ground, having been removed there merely as housemates of the primary patient; it must not be supposed that in any case there was good reason to think that the infection had been received by direct communication from the primary patient. Thus, as regards the first four contact cases mentioned at the beginning of March (D——), the infection was clearly received about the same time in the same place; in the second instance the second patient fell ill immediately after his removal; and in the third and fourth cases now added illness began 24 and 48 hours after removal respectively. The true history of the infection of five of the eight members of the D—— family seems now to have been got from the father since his recovery. It was at first thought that the four children had been in the habit of playing on a very extensive rubbish heap to which wastes continued to be removed by the city council long after the wharves from which much of it was taken had become a manifest centre of infection. Subsequently it appeared probable that the children never had been on this heap at all. Lastly, D——, after his recovery, said that a certain little outhouse in the yard attached to his cottage, which was used to hold both dirty linen and discarded bits of carpet, &c., was a place in which the younger children played; that as soon as the youngest child had been removed to the hospital where he died he cleaned out this place and found under the clothes and rags four dead rats. It has been noted already that these premises were full of fleas in extraordinary number and that the children were covered with their punctures from head to foot; it is now to be observed that the only members of the family attacked were the younger children and their father who cleaned out the place in which they often played.

Thus it seems that evidence of infectiousness is as much

wanting at this date as it was earlier in the epidemic. From this point of view, however, the following occurrence has more interest. A girl was taken from a cottage, occupied by a small family, all of whom were removed as contacts; after five days' detention, during which the cottage was disinfected and cleansed, the family returned. The patient had but a moderate illness and an inguinal bubo which did not suppurate; she was discharged at the end of 23 days in very good health and rejoined her family. Ten days later a little boy was attacked with plague. As far as can be learned he must have received the infection in the cottage from which he had not been away, and there is no doubt at all as to the disinfection and destruction of the original patient's personal clothing, all other material in the cottage having been disinfected by steam or otherwise and having been used by the family (including the second patient) during all of the 33 days between the removal of the girl and the attack of the boy, except the first five of them. The cottage was very well kept and stood in a good street in a poor neighbourhood; it was properly connected with the sewers and with the water-service. But it was a survival from older days; it was built of weatherboard, the joists almost touched the earth, and the floors were rotten and shaky. Rats had been present before removal of the first case, but in no great number, and it was said that none at all had been seen since the family had returned. The locality was within a few hundred yards of the rubbish-tip already mentioned. The floors have not yet been torn up, but this will be done, and half a dozen similar cottages in the street will be presented to the local authority as unfit for habitation.

The past week has yielded more cases by nine than any previous week, and it is now evident that the localities in which the infection is present extend to a much greater distance from the primary infected area than hitherto. Nevertheless, a large proportion of cases can be connected with that area by employment within it, although the number occurring in rather distant neighbourhoods, whose infection cannot at all be accounted for on that hypothesis, steadily increases. Plague rats have now been found in many different neighbourhoods also, but the connexion between them and new cases has not been as thoroughly examined as it was hoped would be the case, the scarcity of rat-catchers or the disinclination of any there may be to continue their business at this critical juncture being surprising.

The bacteriologist to the Health Department (Dr. Frank Tidswell) has observed the bacillus in the intestinal contents of a flea taken from a plague rat. Simond is doubtless right in saying that fleas taken by him from rats in India were grey; whether there be any flea peculiar to the rat here and distinguishable by others than entomologists from ordinary kinds is an unanswered question. All that can be said is that those so far examined have presented the usual appearances, being from reddish-brown to blackish-brown in colour, and of all sizes up to that of the monster popularly associated with dogs. Valerio-Galli's remarks on this topic[1] are hardly convincing and in one respect at least unphilosophical; his rat-fleas would not bite him; but that proves nothing, for no flea whatever will bite the present writer, and many other people doubtless, nor does Netter[2] for a similar reason contribute anything of importance to the subject. There is hope for some, therefore, that they may escape infection by fleas even without the aid of the neat velvet bracelets and anklets containing formic aldehyde in some form, which an ingenious French manufacturer has put upon the Paris market.

The specimen of Yersin-Roux serum referred to in my last letter turns out to have been forwarded in response to the well-meant interference of the Consul-General for France. The Pasteur Institute had already sent to the Agent-General at London four litres for transmission to the Government and they are expected to arrive very soon. Other consignments of the ten litres asked for are to follow. Everyone was puzzled by the occurrence thus explained, our French fellow citizens who are cordially liked and deservedly esteemed not less than others. Nor was it seriously supposed that the directorate of the Pasteur Institute would disregard the cry of their fellow men in distress without mention of some necessity by which they were compelled.

[1] Archiv für Bakteriologie.
[2] La Peste et son Microbe, p. 73.

The Government has undertaken resumption of the line of wharves so often referred to in this connexion, and of property at the back of them, with a view to reconstruction; the expenditure will be between £3,000,000 and £4,000,000 sterling. Quarantining and cleansing of successive areas still continue. It is noteworthy that only one of the men engaged on this work has taken the disease; the number employed has usually, or on an average, probably been 1500, but it has run up to near 3000, and in several weeks has been 2000.

May 7th.

THE UNIVERSAL EXHIBITION AT PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

SURGICAL INSTRUMENTS AND FURNITURE.

GROUP III. is devoted to letters, science, and the arts, and Class 16 within this group is entitled Medicine and Surgery. This class situated at the extreme end of the westerly wing of the main building on the Champ de Mars and close to the Eiffel Tower. On entering at this point and turning to the left the word "Surgery" is written upon one of the partitions; but on passing within I was at once assailed by anxious inquiries as to my eyesight, and one eager exhibitor was particularly desirous that I should try a pair of pebble spectacles. Gently releasing myself from these allurements I was next subjected to suggestions that I really ought to provide myself with some elegant opera-glasses; but I pushed towards a row of trumpet-mouthed phonographs which, though they sang or spoke, yet did not urge me to buy. Now I came upon a discreetly walled-off partition so built that the passing crowds could not see what might be exhibited within. Doubtless this was an arrangement to prevent nervous persons from being shocked by coming suddenly upon some sinister anatomical model or specimen. Making a mental note of this delicate discretion, I braced up my nerves and entered the compartment, quite prepared to see loathsome models of lupus or some other repugnant malady. To my surprise I found myself in a delightful oasis of theatrical scenery. On all sides there were small stages about two feet square, brilliantly lighted from within, and on each stage one of the most elaborate and romantic scenes from a well-known play or opera. It was very pretty, very interesting, very ingenious, and made me feel quite sorry that I was not a theatrical critic. There was, however, not even any indication as to how these model stages were warmed or ventilated, so I had no pretext whatsoever for remaining in this charming little exhibit; and then it occurred to me that, as Class 16 was undoubtedly in this part of the building, it must be in the large gallery above and not on the ground floor. Having ascended the nearest flight of stairs I found myself at once face to face with a life-size model of an individual, perfect in every respect, excepting that he had no skin and therefore exhibited his muscles, nerves, and the like. There was no walling off here, no discreet curtain, which only those who were interested in such subjects might remove. The anatomical wax models are fully exposed and no one passing near can avoid seeing them, but they are not numerous. Close by, and labeled "Microphotography of the Broca Hospital, gynæcological service of Dr. Pozzi," is a large collection of coloured photographic enlargements of microbes. There is here the subject-matter of a useful study, and this exhibit will not fail to attract considerable attention among practitioners who treat more especially the diseases of women.

Close by are numerous exhibits connected with the treatment of various diseases, such as, for instance, the Maison Puy-Laurent for bandages, trusses, &c. This firm has a contrivance by which the pad of a truss is replaced by an india-rubber bag. When in proper position the rubber bag can be filled by a funnel with liquid plaster which, drying in from 10 to 15 minutes, constitutes a very exact model of the shape and size of the pad required. M. A. Maugeon, M. E. Morin, and M. C. Regnier, all of Paris, exhibit suspenders, bandages, stockings for varicose veins, corsets, and orthopædic apparatus, &c. Messrs. Mantelet et Fils have seamless elastic stockings and M. Abrioux has orthopædic boots and shoes. M. A. Bruyge makes wooden legs and other artificial

limbs, and M. F. Lacroix makes ventilated orthopædic supports, &c. M. L. Gaillard has a very large assortment of sounds, bougies, and cannulæ that can be easily sterilised; while Messrs. Bühler et Cie have some small flexible metal tubing through which gas, water, or vapour can be passed under pressure. This tubing can be bent round and round so as to form a cone or cap that may be placed on the head of a patient and when fed with a cold current of water would replace an ice-bag. In the same manner the tubing may be twisted round a limb and applied for many and various purposes.

Amid many other exhibits of this character the firm of Messrs. Flicoteaux, Borne, and Boutet show an operating-room and all the appropriate furniture. On an enamelled hardware slab or table four thick glass basins are placed. Above, suspended to the wall, four glass reservoirs provide water for these basins which flows from a small nickel tube and the water is turned on by placing the foot on a lever below. In the centre of the table there is a trapped drain-pipe to carry away the dirty water. It all appears to be quite aseptic; but on passing my hand underneath this washstand I found that it was only the upper outer surface that had been enamelled and that dust was adhering to the hardware which underneath had been left in a rough and unglazed condition. How far this is porous I cannot say, but all who have had experience in testing drain-pipes are aware that hardware is porous and does absorb water. If enamelling is necessary above where dirt can be seen and washed away, it is still more necessary underneath where dirt and dust cannot be seen. The operating-table close by is probably the simplest table in the Exhibition. It consists of a small slab of opaline—i.e., a mixture of glass and porcelain. By a wheel and crank it can be lifted or made to slant, but to hold the limbs in a bent position attachments have to be affixed to this one rigid slab. Simplicity of structure and the aseptic nature of the material used is about all that can be said in favour of this operating table. But the same firm exhibits a stretcher on wheels, designed by Dr. Monprofit, and so contrived that the patient can be replaced in his bed without being lifted off the stretcher. The patient lies on two thin slabs of enamelled metal held close together by an iron frame. This can be lifted off the wheels and placed on the bed. The frame is then unscrewed and the slabs, thus released, can on each side be easily drawn away from underneath the patient. Messrs. Flicoteaux, Borne, and Boutet have supplied many well-known hospitals with their various products.

M. S. Favre of Paris, exhibits a new pocket bistoury. It is in a small case, only three inches long, containing a handle and six different sorts of blades. He also shows sterilisers in which ebullition is produced very rapidly.

M. R. Mathieu of Paris has several interesting exhibits, and notably the Déchery cautery. This is composed entirely of metal. The hollow handle is charged with ether. A little spirit lamp is fitted to the case which contains the cautery. When warmed over this lamp the platinum point becomes red hot in two minutes and remains in that condition while the supply of ether lasts. There are also some very ingenious crushing clamps and clamps for seizing, without injuring, the intestines. For the latter purpose there is on one side a metal oval-shaped ring covered over with an indiarubber glove-finger. Opposite a small rod is also covered with indiarubber. The handle, like that of a pair of scissors, brings this rod against the soft centre of the indiarubber covering on the oval side. Thus the pressure of metal against metal is avoided. This firm has distinguished itself in the manufacture of dynamometers. For the most part they have the shape of a vesica about five inches long by two and a half inches in the centre or broadest part. It can therefore be conveniently held in the centre of the hand and squeezed. The novelty consists of clockwork in the centre which records the number of seconds the pressure continues and gives a loud tick when the muscular effort ceases to produce any further result. A handle records on a dial and in grammes what that pressure has been. By passing a finger from each hand inside the extremities of the oval or vesica the power of pulling asunder can then be tested, the result being similarly recorded. To other dynamometers a vesica is attached, large enough to be placed under the arm or between the legs, and the power of squeezing the legs together or of pressing the arm against the side can be ascertained. Thus four different tests can be made with the one instrument. This is often necessary. By holding the dynamometer in one hand and squeezing I found that the representative of the firm who showed me these instruments was very much stronger than I am. But when I took the instrument with both hands and tried to pull it asunder it was demonstrated that my pull was stronger than his. Thus one single test would have conveyed a totally false impression of our respective strengths. These instruments cost from 35 francs to 150 francs. Colonel de Rochas, Director of the Polytechnic Military School, in his "*Exteriorisation de Motricité*," remarks that persons holding Eusepia Pallidino's hands generally complained of great exhaustion at the end of 20 to 30 minutes. This led him to employ a dynamometer of this description, and he thus discovered that after experiments during which remarkable phenomena are said to have been produced the persons present had between them lost enough strength to make up the strength of an average adult. There is also a dynamometer made for the purpose of estimating with great precision the amount of pressure necessary to reduce hernia. Finally, it may be noted that this firm also manufactures the apparatus used for straightening malformations due to Pott's disease or spinal curvatures, and which is employed at the celebrated hospital of Berck-sur-Mer.

Unfortunately for these exhibitors they are very badly situated. The Exhibition is so large, people are so soon tired that many have not the courage to go up to the galleries. When, however, they do ascend to these upper regions they soon discover that they are much nearer to the glass roof of the great gallery and therefore feel the heat much more intensely. In fact, the atmosphere is that of a hothouse. The ventilating fans that are exhibited and stand idle in their particular section might here be put to a very useful practical test. Downstairs in the British section, I found but one exhibitor of hospital furniture and surgical instruments. This was the firm of Messrs. Down Brothers, and they have manufactured a new operating table expressly for the Exhibition. The table is on wheels, or rather on large improved casters that are on ball bearings like those used for bicycles. Therefore the table, in spite of its great weight and the weight of the patient who may be on it can be moved about with the utmost facility and with hardly any effort. Similar casters are used for all the other furniture and are particularly useful for the very heavy instrument cabinets. These, in consequence of their weight, are apt to be left indefinitely in their position against a wall. Consequently the space behind does not get cleaned. But now there will be no excuse for not washing and dusting behind as well as in front of all such furniture, since it is so easily moved. With regard to the operating table, if it is convenient on certain occasions that it should be moved without effort, it is essential that during an operation it should be absolutely steady. Consequently there is a lever arrangement by which the casters are raised and the table then rests on broad, flat feet and a very strong push will not move it. The next point is that due account has been taken of the fact that operating surgeons, like other mortals, vary in stature. The table is so built that its general level can be raised or lowered for a distance of nine inches so as to suit each individual operator, whether tall or short. The surface is of perforated nickel-plated metal. Underneath this there is a metal trough bed draining in the centre. The head, trunk, and limbs of the patient can be raised or lowered and put in any position. There is also a rest that can be attached to any side of the table, to support a leg or an arm or to serve as an instrument tray. The framework of the table is made of tubes, through which hot water can be made to circulate. The attachments are so arranged that the whole or only a part of the table can be heated, and if any portion of the body is raised so are the hot-water tubes; therefore the patient is not removed from the heat-giving surfaces. There is an extra trough for douching in lithotomy, &c., and this can be added to either end of the table. All the joints are of gun-metal, this, with nickel and glass, being the only materials employed for the operating room furniture. Where a glass shelf is used the corners are rounded off, so that everything is easily cleaned. The screw portion for raising the operating table is covered over, so that dust cannot lodge in the indentures. The framework of all the furniture is of drawn metal and there is no soldering, so that it cannot come to pieces. A large glass cabinet contains many beautiful instruments, notably a new cutting forceps for the resection of

ribs, the blade pressing down on a slot which is open in the centre. Then there are Beter's bone forceps. When the bone is properly gripped the forceps can be fixed by means of a screw contrivance in the handle. The operator's hands are then free to apply the sutures, &c. The lithotrite suggested by Mr. H. M. N. Milton of Cairo may also be seen here. It is so arranged that the crushed stone can be evacuated through the handle without withdrawing the instrument. The entire exhibit takes the form of a model operating theatre. The floor is of mosaic set in hard cement on a metal base and the walls are of glazed tiles fixed also in cement. Many other interesting objects are to be seen here, making altogether a very complete surgical exhibit.

Of course there is much more appertaining to Class 16 shown elsewhere, both in the French section and among the exhibits of other nationalities, but a description of what has been omitted must now be deferred to another occasion.

Paris, June 18th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Home for Epileptics, Maghull.

THE annual meeting in connexion with the "Home for Epileptics" at Maghull, near Liverpool, took place on June 16th, under the presidency of the Lord Mayor. There were 120 patients in the institution at the beginning of 1889. During the year 20 patients were discharged, 4 had died, and 27 were admitted, leaving 123 inmates at the end of 1899. Arrangements had been made with the Education Department for carrying on during the past winter an evening continuation school and also for giving technical instruction to such patients as were capable of receiving it. The school had proved a great success and the managers are in hopes of receiving a Government grant towards the expenses. The plan of remunerating patients able and willing to undertake fixed duties had proved satisfactory, and in many instances the remuneration received had been equivalent to the value of their maintenance, the cost of rent and nursing being provided partly by payments of friends and partly by donations. To enable them to carry out the project the committee are desirous of a sum of £750 to meet the initial expenses of buildings, implements, and stock, and a guarantee fund of £250 a year for five years towards rent and nursing. It would be possible to purchase a suitable farm in the neighbourhood of the present "home" if a sum of £5000 could be raised for that object. In order to bring about a better social classification of the patients it had been decided to acquire a portion of the park land adjoining the "home" and to erect a suitable building, with nurses and servants, and for this purpose the committee had appealed for £3500. The finances were in general in a satisfactory condition. The medical records of the home showed a decided improvement in very unpromising cases. The institution at Maghull, which mainly owes its origin, among others, to Dr. William Alexander of the Royal Southern Hospital and the Workhouse Hospital, was established 11 years ago and was the first of its kind in the kingdom. The Lord Mayor said that a portion of the Manchester money of the David Lewis Trust was to be devoted to the establishment of a similar home near Manchester. The Lord Mayor promised to give a donation of £50 to the Maghull Home.

Hospital Saturday Fund: Ladies' Street Collection.

The annual street collection made by ladies on behalf of the Hospital Saturday Fund took place on June 9th. The collection realised £837 10*s.* 11*d.*, which is about equal to the sum collected last year.

Death of Mr. Alfred Fisher, M.R.C.S. Eng., L.R.C.P. Edin.

Much regret is felt at the death of Mr. Alfred Fisher, which took place on June 17th from pneumonia after a very short illness. Up to the last few days he had been apparently in robust health, but he was taken suddenly ill during the night of June 14th. Mr. Fisher, who was only 37 years of age, was formerly house surgeon at the Northern Hospital. He was of an extremely affable disposition and much sympathy is felt for his widow and child.

The Health of St. Helens in 1899.

The annual report on the health of the borough of St. Helens, by Dr. Drew Harris, the medical officer of health, stated that the birth-rate for 1899 was 35·97 per 1000 of the population, or 2·52 per 1000 lower than the preceding year. The death-rate was 19·16 per 1000, or 0·27 per 1000 above the previous year, and 2·2 per 1000 below the average of the preceding 10 years. It was the lowest death-rate except two on record for the borough. A satisfactory feature of the report was the great saving of infant life during the year which had been brought about by the expenditure of time and money which the Health Committee had devoted to the subject. The rate of mortality among infants during the year was 157 as against 172 in the preceding year, and a mean rate of 172 in the last 10 years. The rate for England and Wales last year was 163. This was the first occasion upon which the infant mortality rate in St. Helens had been lower than that of England and Wales. In the early part of the year a list of all the births registered in the borough was obtained from the registrar in order that the female sanitary inspector might visit the parents and leave instructions as to feeding. A depôt upon the model of that at Fécamp and at Havre was opened later in the year for the supply of sterilised humanised milk, which had proved a great boon to the infants of the poorer class. The death-rate from typhoid fever was 0·49 per 1000, or 0·03 below the mean for the previous 10 years. The number of cases notified was 221, but the mortality was relatively smaller than in the previous year. The estimated population was 86,588; the total births were 3115, and the deaths were 1700.

June 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Medical Association and the Superannuation of Medical Officers.

A DEPUTATION consisting of Sir Thornley Stoker and other members of the Irish Medical Association, waited on Mr. John Redmond, M.P., at the Imperial Hotel, Dublin, on June 18th with respect to the superannuation of medical officers. Dr. Joseph Smyth of Naas stated the case on behalf of the Irish Poor-law medical officers with much ability. He remarked that the Superannuation Bill now advocated by the Association provided that the allowance should be paid not from the rates but out of the contributions made by the medical officers themselves. Mr. Redmond, in replying to the deputation, said that the objects of the Association met with his entire sympathy and he promised, moreover, that when the Bill came before Parliament the support of the Irish national party might be relied upon.

The British Association.

On June 13th a public meeting summoned by the Lord Mayor in response to a numerously signed requisition was held in the council chamber of the town-hall, when, on the motion of the Earl of Shaftesbury, D.L., seconded by the President of Queen's College, it was decided to renew the invitation to the British Association to visit Belfast in 1902. A representative deputation was appointed to present this invitation at the forthcoming meeting of the Association in Bradford. The last meeting in Belfast was in 1874 when the President (Professor Tyndall) and Professor Huxley gave their famous addresses.

Londonderry City and County Infirmary.

A special meeting of the committee of management of the Londonderry City and County Infirmary is to be held next week to consider the question of the proposed rearrangement of the medical staff. Previously to the death of Sir W. Miller, there was only one extern medical officer, but a sub-committee who were appointed to consider the future management of the institution have after careful consideration and after having received suggestions from the medical men of the city and county of Londonderry recommended that there should be an honorary visiting staff and a resident surgeon. They also advise that the resident surgeon should have full charge of the management and administration of the infirmary as directed by the committee of management and give assistance to the visiting staff in all cases. They recommend that the extern staff should consist of two physicians, two surgeons, and one anæsthetist.

The Belfast Hospital for Sick Children.

Dr. Brian O'Brien has been appointed assistant surgeon to the Belfast Hospital for Sick Children in place of Dr. James Lynass, resigned.

June 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Experimental Treatment of Tuberculosis by means of Raw Meat and Meat Juice.

M. Richet and M. Héricourt, pursuing the line of research which they have already undertaken and which I mentioned in a previous letter, communicated to the Society of Biology at the meeting held on June 2nd the latest results which they have obtained. They inoculated a certain number of dogs with tuberculosis and separated them into three groups. The dogs composing the first group were fed upon ordinary food and died at the end of three or four weeks. Those in the second group were fed upon cooked meat and lived very little longer than did those in the first group. Those in the third group were fed solely upon raw meat and remained in perfectly good health at the end of six months from the beginning of the experiment. The curative influence which a raw meat diet possesses over tuberculosis experimentally produced in dogs is thus established, for it is almost unknown for a tuberculous dog living under ordinary conditions to last for more than three months. Raw meat juice appears to have the same action as that of raw meat. M. Richet and M. Héricourt have also ascertained that this effect of raw meat has a prophylactic as well as a curative action. Two dogs which had been fed for many months upon raw meat and meat juice were inoculated and are alive at the present moment despite the fact that after the inoculation they were taken off the special diet and put upon ordinary diet. Control dogs inoculated at the same time, but which had not been prepared by being fed upon the special diet beforehand, are dead long ago. The two observers have also investigated the dose necessary to obtain success. One dog received a daily dose of raw meat in the proportion of five grammes per kilogramme of body weight. Another received 12 grammes per kilo., a third 32 grammes per kilo., and a fourth 64 grammes per kilo. The first dog died while the three others remained well. M. Richet and M. Héricourt therefore consider that to preserve a dog from the effects of an inoculation of tubercle it must be given a minimal dose of from 10 to 12 grammes per kilo. of body-weight every day. The active principle is evidently a soluble substance, for if the meat is chopped up and pressed to deprive it of its juice, a second pressing after moistening with water produces an absolutely inactive fluid, even after the meat has been allowed to soak for 24 hours. These facts confirm the results formerly obtained by Malassez and Vignal who laid stress upon the importance of muscular "opotherapy" in tuberculosis. They had noticed that tubercle never developed in muscles and concluded that meat juice contained some plasma inimical to the evolution of tubercle.

The Increase in the Paris Supply of Drinking Water.

The supply of water from the springs of Loing and Lunain, works for which have been in progress for many years, are now complete. The aqueduct is 100 kilometres in length, the quantity of water delivered is ample, and the works cost 24,000,000 francs. By this means even during great spells of heat Paris will have a plentiful supply of drinking water, and the fears which have been entertained of a water famine during the Exhibition are shown to be unfounded.

The Small-pox Epidemic at Lyons.

The epidemic of small-pox at Lyons still continues. The populace is very averse to revaccination, and to lessen the necessity for the workman losing half a day's work by having to attend at the vaccination station the public vaccinators are offering vaccination at workmen's houses, going from door to door to try to persuade the people to profit by revaccination. M. Roux and M. Pic have tried this plan in the working-class quarter, but have been met everywhere by formal refusals. Out of 700 hands employed by one firm only 10 have consented to be revaccinated and that only by a medical man specially supplied by the head of the firm. M. Rafin, acting in similar circumstances, has only been able to revaccinate 20 out of 300 hands. He considers that the dry sweeping (*balayage à sec*) of staircases which is the custom in Lyons is a fruitful cause of the dissemination of infectious diseases and M. Delore makes the same remark in so far as regards the custom of beating carpets in courtyards.

The Geographical Distribution of Goitre in France.

At a recent meeting of the Academy of Medicine M. Poncet of Lyons communicated to the Academy the results of some statistics drawn up by M. L. Mayet relative to the distribution of goitre in various districts of France. The figures on which the statistics were based were taken from the returns furnished by provincial councils of the physical examination of recruits enrolled each year. These documents, which cover the period 1887–1896, have enabled M. Mayet to divide the departments of France into six groups classified according to the number of cases of goitre per every 1000 conscripts. The classification shows plainly that goitre is not distributed in a haphazard way, for the departments most effected are grouped in blocks occupying the regions of the Alps, the Pyrenees, the Central Plateau, the Jura, and the Vosges. The departments of the Aisne and the Orne alone show up as black spots in otherwise unaffected districts. M. Mayet has compared these figures with others for past periods, the one from 1816 to 1825 and another from 1836 to 1845. He concludes from these that the distribution of goitre is still much the same as before but that its amount has diminished, especially within the last 50 years. The number of those affected with goitre in France has diminished but it is not known exactly in what proportion. M. Mayet considers that probably the total number of goitrous people is between 375,000 and 400,000.

June 19th.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the Congregation on June 14th the following degrees were conferred:—

Degree of Doctor of Medicine.—J. W. Cornwall, Trinity; and W. E. Alston, Clare.

Degree of Bachelor of Medicine.—E. W. Hedley, King's; and R. S. Trevor, Clare.

Degree of Bachelor of Medicine and Bachelor of Surgery.—W. S. Darby, Trinity; J. H. Tallent, St. John's; G. F. Lobb, Caius; S. P. Pollard, Caius; J. W. Malim, Christ's; T. Burfield, Emmanuel; and D. G. Hall, Emmanuel.

Degree of Bachelor of Surgery.—L. J. Paton, Caius.

At the examinations for medical and surgical degrees, Easter term, the following candidates were successful in the subjects indicated:—

FIRST EXAMINATION.

Part I., Chemistry and Physics.—W. A. Alexander and E. E. Atkin, Caius; R. L. Barwick, Christ's; H. Beckton, M.A., Clare; A. E. Bellars, Magdalene; P. Black, Caius; C. W. Bowle, Trinity; R. Burgess, Caius; G. G. Butler, Emmanuel; D. V. Cow, Trinity; F. D. Crew, Emmanuel; J. N. F. Fergusson, St. John's; A. C. D. Firth, Trinity; R. L. Gamlen, Caius; H. P. B. Gough and G. F. Greenwood, Sidney Sussex; J. M. P. Grell, H. Selwyn; H. S. Hall, Pembroke; G. S. Haynes, King's; A. W. Hayward, St. John's; R. A. P. Hill, Caius; W. H. Hodgson and R. Hoisington, Christ's; C. W. Hutt, Trinity; T. A. Jones, Caius; W. D. Keyworth, H. Selwyn; F. P. Luard, Downing; A. Morris, A. H. Owen, and M. Phillips, Caius; W. O. Pitt, Emmanuel; S. B. Priston, St. John's; A. C. H. Rothera, Emmanuel; C. E. F. Salt, Pembroke; F. S. Scruby, H. Selwyn; E. F. Skinner, Corpus Christi; P. H. Smith, Pembroke; P. L. Stallard, Caius; B. S. Taylor, M.A., Clare; R. S. Taylor, Downing; H. A. R. E. Unwin, H. Selwyn; J. A. Venning, Trinity; G. L. Webb, Caius; C. W. H. Weekes, H. B. Weir, and W. de L. Winter, Trinity; and H. N. Wyman, Caius.

Part II., Elementary Biology.—W. A. Alexander and E. E. Atkin, Caius; J. B. Banister, Jesus; E. Beaton, Caius; H. Beckton, M.A., Clare; A. E. Bellars, Magdalene; T. R. H. Blake, Pembroke; C. W. Bowle, Trinity; W. T. Briscoe, H. Selwyn; G. G. Butler, Emmanuel; A. F. Comyn, Pembroke; A. I. Cooke and H. B. Corry, Caius; D. V. Cow, Trinity; E. A. Crossley, Clare; R. Davies-Colley, Emmanuel; E. F. de Clermont, King's; A. N. Dickson, Downing; J. N. F. Fergusson, St. John's; A. C. D. Firth, Trinity; R. L. Gamlen, Caius; L. H. Gob, Emmanuel; G. W. Goodhart, Trinity; H. P. B. Gough, Sidney Sussex; W. B. Gourlay, Trinity; W. B. Grandage, Clare; H. T. Gray, Trinity; G. F. Greenwood, Sidney Sussex; J. M. P. Grell, H. Selwyn; H. S. Hall, Pembroke; Eric F. Harrison, Trinity; G. S. Haynes, King's; A. W. Hayward, St. John's; R. A. P. Hill, Caius; R. B. Hoisington, Christ's; C. W. Hutt, Trinity; R. S. Jenkins, St. John's; T. A. Jones, Caius; W. D. Keyworth, H. Selwyn; B. T. Lang, Trinity; H. M. J. F. de P. P. Leite, Caius; C. Lillingston, Pembroke; J. W. Linnell, St. John's; F. P. Luard, Downing; S. G. MacDonald, St. John's; J. McIntyre, King's; A. W. Moore, Emmanuel; A. R. Moore, B.A., and H. F. G. Noyes, Caius; G. G. Packe, Trinity; F. W. M. Palmer, B.A., Jesus; W. O. Pitt, Emmanuel; H. W. Pocock, Caius; S. B. Priston, St. John's; E. S. Purkis, H. Selwyn; A. C. H. Rothera, Emmanuel; D. W. Roy, Sidney Sussex; F. S. Scruby, H. Selwyn; R. B. S. Sewell, Christ's; P. H. Smith, Pembroke; P. L. Stallard, C. Strickland, and A. C. H. Suhr, Caius; D. W. Tacey, B.A., Christ's; R. S. Taylor, Downing; H. A. R. E. Unwin, H. Selwyn; B. Wallis, Trinity; G. H. H. Waylen, King's; G. L. Webb, Caius; H. B. Weir, Trinity; W. P. Williams, Downing; W. de L. Winter and J. L. Wood, Trinity; L. Worrall, B.A., Christ's; and H. N. Wyman, Caius.

SECOND EXAMINATION.

Part I., Pharmaceutical Chemistry.—L. J. Austin, Sidney Sussex; A. L. Baly, Emmanuel; A. S. B. Bankart, Trinity; J. D. Barris, Caius; E. Bell, Clare; G. L. Cox, Christ's; L. G. Davies, Trinity

T. Drysdale, Jesus; N. C. Fletcher, B.A., Queens'; R. E. French, King's; F. M. Gardner-Medwin, B.A., Trinity; T. R. Glynn, Clare; R. E. G. Gray, Pembroke; S. A. Henry, Trinity; R. F. V. Hodge, Emmanuel; W. G. Howartb, King's; E. C. Hughes, Clare; C. L. Isaac, B.A., St. John's; C. King, Trinity; H. E. Kitchen, B.A., Sidney Sussex; R. Leslie, B.A., Pembroke; S. M. Mackenzie, Trinity; E. H. Mayhew, Emmanuel; J. B. Mennell, Pembroke; S. H. Nixon, Emmanuel; W. H. Rayner, Trinity; W. H. Robinson, Downing; F. F. Shout, Caius; G. C. E. Simpson, St. John's; P. S. Stephens, Trinity; W. H. E. Stewart, Caius; and F. P. Young, Christ's.

Part II. Human Anatomy and Physiology.—H. Ackroyd, B.A., Caius; A. E. Barclay, B.A., Christ's; H. N. Burroughes, B.A., Trinity; H. J. Cardew, B.A., Clare; R. A. Clapham, B.A., Emmanuel; J. G. Cooper, Trinity; J. S. Cooper, B.A., Jesus; W. B Crowfoot, B.A., Emmanuel; C. W. Cunnington, B.A., Non-Collegiate; W. F. L. Day, B.A., and J. H. Donnell, B.A., Caius. T. R. Elliott, Trinity; R. B. Etherington Smith, B.A., Trinity; J. E. Frere, B.A., Pembroke; F. Gayner, B.A., King's; H. U. Gould, B.A., Trinity; G. W. Greene, B.A., Downing; C. F. Hardie, B.A., Queen's; P. Hardy, B.A., Trinity Hall; E. T. Harris, B.A., Christ's; N. G. Harry, B.A., Jesus; A. W. Harvey, B.A., St. John's; H. G. L. Haynes, Downing; W. H. Hills, B.A., Pembroke; B. Hudson, B.A., Clare; J. Lambert, Downing; P. W. Leathart, B.A., Clare; W. E. Lee, B.A., and R. C. Mott, B.A., Trinity; C. M. Murray, B.A., Pembroke; P. K. Muspratt, B.A., Christ's; G. B. Norman, St. John's; P. N. Panton, B.A., Trinity; O. V. Payne, St. John's; J. S. Pearson, B.A., Trinity; H. I. Pinches, B.A., Sidney Sussex; C. A. W. Pope, B.A., Trinity; G. R. Rickett, B.A., King's; R. H. Robbins, B.A., Trinity; J. N. Robins, B.A., and T. Sanders, B.A., Christ's; H. C. Sidgwick, B.A., and J. G. Slade, B.A., Clare; T. D. Smith, B.A., Jesus; L. E. Wigram, B.A., Trinity; and S. L. O. Young, B.A., Christ's.

VICTORIA UNIVERSITY.—The Council has decided on the award of the following degrees, which will be conferred by the Chancellor, Earl Spencer, K.G., on June 30th, at the Free Trade Hall, Manchester:—

Degree of Doctor of Science.—H. T. Ashton, W. H. Bentley, F. W. Gamble, and George Wilson, Owens.

Degree of Doctor of Medicine.—Hubert Armstrong, University, and Alfred Greenwood, J. A. MacLaren, W. A. Newall, and F. W. Stansfield, Owens.

FOREIGN UNIVERSITY INTELLIGENCE. — *Baltimore (Johns Hopkins University):* Dr. F. S. Cullen and Dr. W. W. Russell have been appointed Professors of Gynæcology.—*Berlin:* Dr. Albert Eulenburg has been promoted to an Extraordinary Professorship. He was formerly Professor of Pharmacology in the University of Greifswald.—*Bologna:* Dr. Serafino Patellani of Parma has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Chicago (Rush Medical College):* Dr. Henry Favill has been appointed Professor of Therapeutics.—*Genoa:* Dr. Angelo Becco of Rome has been recognised as *privat-docent* of Topographical Anatomy and Operative Medicine, and Dr. Rocco Iemma of Naples has been recognised as *privat-docent* of Pædiatry.—*Göttingen:* Dr. A. Cramer has been appointed to the chair of Psychiatry.—*Gratz:* Dr. Alois Birnbacher, Extraordinary Professor of Ophthalmology, has been promoted to an Ordinary Professorship.—*Halle:* Dr. Schick has been recognised as *privat-docent* of Ophthalmology.—*Heidelberg:* Dr. Göppert has been appointed Extraordinary Professor of Anatomy.—*Innsbruck:* A new chemical and pharmacological institute has just been erected.—Dr. Stephan Bernheimer of Vienna has been appointed Professor of Ophthalmology.—*Kiel:* Dr. Paul Sick has been recognised as *privat-docent* of Surgery.—*Königsberg:* Dr. Oscar Samter, *privat-docent* of Surgery, has been promoted to a professorship.—*Naples:* Dr. Tommaso Guido and Dr. Ettore Somma have been recognised as *privat-docenten* of Pædiatry, and Dr. Giovanni Graziani has been recognised as *privat-docent* of Medical Pathology.—*Padua:* Dr. Arslan of Turin has been recognised as *privat-docent* of Otolaryngology.—*Palermo:* Dr. Fortunato of Genoa has been recognised as *privat-docent* of Ophthalmology.—*Prague (Bohemian University):* Dr. Kunta has been promoted to an Extraordinary Professorship of Pathological Anatomy; Dr. Carl Kuffner has been appointed Professor of Psychiatry and Neuro-pathology; and Dr. Jaroslav Bukovsky has been recognised as *privat-docent* of Dermatology and Syphilis.—*Rostock:* Dr. Ehrlich has been recognised as *privat-docent* of Surgery and Dr. Scheven as *privat-docent* of Medicine.—*St. Petersburg (Military Medical Academy):* Dr. Gerver has been recognised as *privat-docent* of Neurology and Psychiatry.—*Strasburg:* Dr. Hans Landolt has been recognised as *privat-docent* of Ophthalmology and Dr. Albrecht Funka as *privat-docent* of Midwifery and Gynæcology.—*Vienna:* Dr. A. Elzholz has has been recognised as *privat-docent* of Psychiatry and Neurology.—*Würzburg:* Professor Hess of Marburg has been appointed to the chair of Ophthalmology vacated by the migration of Professor von Michel to Berlin.—*Zürich:* Dr. Paul Ernst of Heidelberg has been appointed Professor of Pathology and General Anatomy.

THE WELLCOME CHEMICAL RESEARCH LABORATORIES.—These recently completed laboratories were opened for inspection on June 18th. The building, which is situated at No. 6, King-street, Snow-hill, is in the Venetian style of architecture, and consists of four storeys. On the first, second, and third floors are located the different laboratories completely equipped for their purposes while the director of the laboratories, has his library and office on the ground floor. The proprietors would appear to have spared no trouble or expense in making the laboratories complete.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Karl Lange, Professor of Pathological Anatomy in the University of Copenhagen, in his sixty-seventh year. He was editor of the Danish medical journal, *Hospitals Tidende.*—Dr. Friedrich Brosin, a well-known Dresden gynæcologist, whilst touring in Saxon Switzerland. He was only 42 years of age.—Dr. Carter Gray, formerly Professor of Neurology in the Long Island College Hospital, Brooklyn.—Dr. Frothingham, late Professor of Ophthalmology in the Ann Arbor University of Michigan.—Dr. Wilhelm Kühne, the well-known Heidelberg Professor of Physiology.

MAIDENHEAD COTTAGE HOSPITAL.—At a special general meeting of the supporters of this hospital, held at the Town Hall on June 15th, a question of revising the rule as to payment by, or on behalf of, patients was considered in consequence of the generous gift of Mr. W. W. Astor of £10,000 to the institution. After some discussion it was decided that "patients may be admitted to the hospital free of charge, but none shall be admitted without security from some substantial person for payment of the expenses of burial in case of death or of removal, except in cases of sudden emergency. In the case of domestic servants in active service or persons in good circumstances the house secretary may make such charge as he deem proper, not exceeding 10*s.* 6*d.* weekly."

THE SCATTERGOOD TESTIMONIAL AND YORKSHIRE COLLEGE, LEEDS.—In May last, at a meeting held in the Philosophical Hall, it was decided to raise funds for a testimonial to Mr. Thomas Scattergood, M.R.C.S. Eng., in recognition of his long and appreciated services to the medical department of Yorkshire College and that it should take the form of a portrait to hang in the medical school. Sir George Reid, president of the Royal Scottish Academy, was the artist selected to paint the portrait, and although it was not finished before Mr. Scattergood's death the likeness is a good one. On June 11th Mr. A. G. Luton, chairman of the council of the college, made the presentation, on behalf of the subscribers, to the family, and Mr. A. K. Scattergood on their behalf afterwards handed the portrait back, to be hung in the medical school. Miss Scattergood was at the same time the recipient of an inlaid wood and silver tea tray as a souvenir, and each member of the family received a bound copy of the resolutions passed by the council and the medical board which testified the esteem in which the late Mr. Scattergood was held by his colleagues. The cash surplus which remains is to be appropriated to founding a prize in the medical school to be called the "Scattergood Prize."

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Midwives Bill.

THE report stage of the Midwives Bill is down for Wednesday, June 27th—the last Wednesday reserved for the consideration of Bills introduced by private Members. It is doubtful, however, whether it will be reached on that occasion, as there are other Bills in front of it. So far the Government has made no promise of facilities for the measure and, indeed, it is understood that objection is taken to certain of its provisions by the Government.

Registered Companies and Medical Practice.

There is a Bill before Parliament this session, introduced into the House of Commons by the President of the Board of Trade, for the

amendment of the law with regard to registered companies. It deals with such large general questions as the issue of prospectuses and the liabilities of promoters and directors, but in addition it contains a clause of special interest to medical men—a clause declaring that it shall not be lawful for companies to carry on the practice of medicine. It is to be feared, however, that the Bill will not become law during the present session. It has not yet been read a second time and so far the Government has been unable to name a probable date for the second reading.

HOUSE OF COMMONS.

THURSDAY, JUNE 14TH.

The Teaching of Infants.

Sir JOHN GORST, Vice-President of the Board of Education, reviewed at this sitting of the House the elementary education system of the country. He dealt at length with the abandonment of individual examination and the introduction of the block system, with the increased duties and powers now devolving upon inspectors in consequence of this change, with the need for more and better facilities for the training of teachers, and with the teaching of infants. In this last connexion, he said, we begin our attempts at education a great deal too soon, just as we leave off a great deal too soon. The child was cooped up in school as soon as he was three years old when he had much better be playing about in the lanes or fields. He had a quantity of information crammed into him which his little brain was quite incapable of assimilating and he was taken out of school at 11 or 12 years to labour for the rest of his life. Infants' schools were, in the phrase of one of the inspectors, storage places for babies. They were instituted not so much for the benefit of the children as to enable the mothers to have leisure to go to work. If the State chose to establish nurseries of this kind they should make them nurseries, and they should assimilate the teachers, of the youngest children at all events, to nurses. He should say that the age of six years was quite early enough to attempt to exercise the human brain and that between six and eight years the kindergarten system of teaching was the only one which was really suitable. On the subject of the feeding of children Sir John Gorst said: It is the general opinion that this is a matter which should be left altogether to private charity, and that the school authorities should not deal with it. I got into a great scrape last year by enumerating some opinions that it was the duty of the school authorities to see that the children were fed before they were taught. I am quite willing to agree that children should be fed by charitable agencies if they can be, but it seems to me that if you compel children to go to school and compel them to receive instruction, then you have the obligation thrown upon you to make some provision by which those children shall be sent to school in a fit state. This is not a private duty thrown on the parent, it is a public duty which the State has a right to insist on being fulfilled; and, if proper laws are made and a proper administration of the law is carried into effect, I believe the cases in which children would be sent to school unfed and unfitted to receive instruction would be extremely rare. One or two examples made of negligent parents would prevent the recurrence of the offence. It is not the poor parent—it is very seldom extreme poverty which causes the trouble as to underfed children. It is generally idleness, or drunkenness, or carelessness on the part of the parents which is at the bottom of the mischief, or it is greediness for the small earnings of the children. It is not, I say, the poor, but the negligent, parent who is the real offender. I believe that posterity will view with surprise and wonder the state of affairs in this matter, and will marvel how this generation was so stupid as to tolerate it.

FRIDAY, JUNE 15TH.

Experiments on Living Animals.

Mr. JESSE COLLINGS, Under Secretary of State for Home Affairs, moved for a return giving certain information with reference to experiments made on living animals during 1899 under Home Office licences.—Mr. JOHN ELLIS complained of the motion not having been made earlier in the session and the return prepared and presented at a period of the session which left Members interested in this subject opportunity for discussion.—Mr. COLLINGS said that although the formal motion was on this occasion somewhat late the return itself was practically ready and would be presented in the course of a week or ten days. In another session, if he had the opportunity, he would endeavour to have the return prepared earlier.—The motion was then agreed to.

Famine and Cholera in India.

Lord GEORGE HAMILTON, replying to questions on this subject, said: The total number of persons on relief works in India, according to the latest accounts, is 5,802,000. The famine was caused by the failure of last autumn's rains and has therefore lasted about seven months. It is absolutely impossible at present to form even an approximate estimate of the number of deaths which it has caused directly or indirectly. In some parts of India, where famine has been aggravated by cholera and small-pox, the mortality, I fear, has been very heavy; in other large districts where the famine is equally severe, but has not been associated with wholesale epidemic disease, the efforts of the Government of India and its organisation of relief have been so successful that the death-rate is hardly above normal. The total number of reported plague deaths from 1896, when the epidemic began, down to last April was 358,685—that is to say, about one death per annum to every 3000 living inhabitants of India. At the present moment the plague mortality in Bombay is lower than at any period in the three preceding years.—Mr. WILLIAM REDMOND asked the noble lord if his attention had been called to the report of Dr. Kloptsch, administrator of the fund raised in New York for the relief of distress in India, and whether he had any information to the effect, as stated in the report, that vultures, dogs, and jackals had been found devouring human bodies left unburied; and whether, in view of the suffering caused by famine and plague throughout India at present, the Government would recommend at once the appointment of a Royal Commission to inquire into the best and speediest method of dealing with the state of affairs now existing in Her Majesty's Indian Empire.—Lord GEORGE HAMILTON: I have seen the telegram of Dr. Kloptsch and have read similar statements in one or two of the numerous reports that have reached me. These statements only apply to the districts, limited in number, I am glad to say, where cholera and small-pox have attacked the famine camps, thus forming a combination which for the moment baffles any administrative palliation. A Commission of great weight and authority was appointed in 1897 to report on the best method of dealing with famine in India, and its suggestions, which were published in 1898 after a most elaborate and searching inquiry, have been of great value; another similar Commission was appointed in 1898 to deal with the plague, and has produced a very important and exhaustive report, part of which only has yet been published. I do not therefore propose at present to advise the appointment of a Royal Commission, though it may hereafter be advisable, when the present epidemics are over, to utilise the experience gained by making it the subject of further reports.—Mr. WILLIAM REDMOND suggested that the Government should at once raise money to relieve the distress.—Lord GEORGE HAMILTON: It is not a question of money. The only method by which you can deal with the enormous number of people who are suffering from hunger over great areas is to aggregate them in camps on healthy sites. Unfortunately, in the west of India there has been no rain for the last seven months and the difficulty is not so much the scarcity of food as the purity of the water. If cholera attacks in its worst form one of the camps it so terrifies the people that they fly in all directions, carrying with them the germs of disease and dying by the roadsides and in the ditches. And the difficulty does not end there even, because not only does the panic affect the people who are congregated in the camps, but it affects the hospital assistants, camp followers, and camp scavengers. I believe that on more than one occasion the European officer after a panic has found himself with but few assistants in the presence of the dead and dying, all the rest having fled. It is due to such a state of things, and not to a lack of money, that the difficulty arises.

The Deaths from Heat at Aldershot.

Mr. GEORGE WYNDHAM made a long statement with reference to this subject. The essential parts were as follows, viz.:—On Monday, June 11th, a field day was ordered at Aldershot and a total of 18,002 men came on parade. The general order in force on all such occasions is that the men are to get their breakfast before starting and that they are to be provided with light refreshments at some time during the day. The method of carrying out that order is left to the regimental authorities. The breakfast consists of bread and tea and there is no reason to believe that any regiment failed to get breakfast before starting. The light refreshment may consist of sandwiches, but the most popular thing with the men is bread-and-cheese. The men dine on their return to camp and very much prefer these arrangements to carrying an emergency ration which would not be palatable unless a prolonged halt were made for cooking it. The light refreshment of sandwiches or bread-and-cheese may either be served out to the men before they start for them to carry in their haversacks or it may be arranged that a canteen cart shall meet the regiment at some specified point. That is a matter entirely for regimental arrangement and one upon which it would be injudicious to lay down uniform regulations. On Monday morning when the troops started there was, the general commanding states, no exceptional heat; on the contrary, he expected rain. But about 10 o'clock great heat began to be felt and as it continued the "Halt" was sounded at 10.30 and the "Cease fire" at 11.15. It was then directed that the men should be marched back as easily as possible and with such periods of rest as their officers commanding might think desirable. During the march back the severe heat was very much felt; a large number of men fell out; 28 men were received in hospital suffering severely from the effects of the sun, of whom four have died; and 29 men suffered slightly. With the exception of the four men the other patients have made rapid recoveries. The whole distance covered by the troops was at the outside about 14 miles and in many cases less. On the question of head-dress, in most regiments the head-dress worn was the field cap. This cap was designed to afford greater protection than the glengarry, which it has superseded in the great majority of our regiments. The problem of designing an ideal field cap is not an easy one. The cap must be sufficiently light and compact to be carried conveniently in the breast or haversack of the soldier when wearing his helmet; and it is also impossible to ignore altogether the soldier's view of what constitutes a smart head-dress. Before this melancholy occurrence the adjutant-general was at work on a sunshade to be attached to the field cap. But the best course is undoubtedly that all men in possession of helmets should wear them in summer-time, whatever the forecast of the weather, and that men, principally in the Royal Reserves, who are still, owing to the exigencies of the war, unprovided with helmets, should not be allowed to undergo severe exertion at a distance from their barracks. The Commander-in-Chief has notified to the general officer commanding, Aldershot, his regret that this course was not adopted, and has directed that it shall be followed in future. Amid much that is regrettable I am glad to know that 14 medical men and an ambulance were in attendance to mitigate the sufferings to which the troops were exposed by a sudden and unforeseen rise of temperature.—Mr. BARTLEY asked whether the head-dress worn on this occasion was not the same as that worn during the manœuvres in 1898, when there were 61 cases of sunstroke.—Mr. WYNDHAM said that in the majority of cases the field cap was in use in 1898.—Mr. BARTLEY inquired whether some promise was not held out in 1898 that there would be a reform in the head-dress.—Mr. WYNDHAM replied that there had been some discussion and that attempts had been made to improve the head-dress. He still held that the better solution was to wear the proper head-dress (the helmet) and not attempt to use the field cap for purposes for which it was not intended.—Sir J. KENNAWAY asked whether he understood aright that the helmet was in future to be universally worn during manœuvres.—Mr. WYNDHAM replied that the Commander-in-Chief had issued instructions that in summer, whatever the weather, the helmet was to be worn, and that troops unprovided with helmets were not to take part in exhausting operations.

MONDAY, JUNE 18TH.

The Deaths from Heat at Aldershot.

On this subject Mr. WYNDHAM read the following report from the general officer commanding at Aldershot—viz., "With reference to your telegram of June 16th, 1900, I have the honour to report as follows: (1) Reports received from commanding officers state that all men had breakfasts before starting for the field day on the 11th inst.;

(2) light refreshments were actually supplied and carried by every unit some in the haversack, but in the majority of cases in transport carts; (3) the only units that did not receive their refreshments on the 'cease fire' sounding were the 5th Worcester Regiment and the 4th Royal Inniskilling Fusiliers. In the case of the 5th Worcestershire Regiment the officer commanding reports that the cart conveying the refreshments went astray during the operations. As regards the 4th Royal Inniskilling Fusiliers, the commanding officer reports that a contractor had undertaken to supply the battalion with bread and cheese. At the hour of the departure of the battalion he failed to appear. A mule cart was then loaded with the refreshments, but, owing to the driver not being acquainted with the locality in which the operations took place, the cart unfortunately did not turn up."

TUESDAY, JUNE 19TH.

Disease and Famine in India.

Mr. MACLEAN asked the Secretary of State for India whether medical authorities in India had condemned the practice of collecting together people seeking famine relief in large camps which were specially liable to attacks of epidemic disease, instead of distributing them near their own homes; whether Mr. Monteath, chief secretary to Government, had reported that it was undoubtedly true that there was not sufficient establishment in India to deal adequately with the demands for relief, and that it was not supposed that the rules and orders of Government were perfectly carried out; and, whether the India Office still considered that the resources of India were sufficient to deal with the famine.—Lord GEORGE HAMILTON replied: I am not aware that the opinion of medical authorities in India is against large relief works. It is, of course obvious that there are some disadvantages in collecting the sufferers from famine in large camps, but the system is on the whole working well and appears to be the only one under which relief on a large scale can be effectively supervised. I have no knowledge of any such report as that which is attributed in the question to a secretary of the Bombay Government. I have reason to believe that although there must be much misery and distress connected with so unparalleled a drought the resources of the India Government as matters now stand are equal to the task undertaken by that Government in respect of the famine.

THE PROPOSED EXEMPTION OF HOSPITALS FROM LOCAL RATES.

The Select Committee of the House of Commons appointed to inquire into the proposed exemption of hospitals from local rates held its first meeting for the examination of witnesses on June 19th. Mr. T. W. Russell, Parliamentary Secretary to the Local Government Board, presided.

Mr. A. D. ADRIAN, legal adviser to the Local Government Board, was the first witness examined. He furnished the Committee with a long statement of the history of the question and the development of the law by means of various judicial decisions. The earliest record he produced was a report of a case decided in the first year of the reign of Queen Anne in which hospitals were held to be liable for rates like other classes of property. In 1760 what was known as the St. Luke's Hospital case was decided by the King's Bench on appeal from Quarter Sessions, the effect of it being that the trustees of the hospital could not be rated as occupiers. On this occasion, however, Lord Mansfield said the judgment carried no general consequences, and each case must be decided upon its merits. Mr. Adrian cited the facts and judgments in relation to the St. Bartholomew's Hospital case nine years later, the York Lunatic Asylum case in 1832, the Bethlehem Hospital case in 1847, and other cases in which hospitals had derived advantage by exemption from rates. He explained, however, that the principles upon which those decisions were founded had no general application. From 1847 onwards there had been frequent decisions in a divergent direction by which property used for charitable and public purposes was held to be liable to rating. Notable among these decisions were that given in the House of Lords in 1865 in the Mersey Docks case, the Ilkley Hospital case in the same year, and the decision in 1875 which declared the Governors of St. Thomas's Hospital liable for rates. The decision against the London County Council in respect of the Erith outfall works in 1893 further defined the interpretation of beneficial occupation, and the general deduction from the judgments given was that local authorities were bound to assess these instititutions in substantial amount. The exemptions from rating included Crown property, parks, some barracks, post-offices, county buildings, churches and chapels, buildings of literary, scientific, and artistic societies, reformatory schools, voluntary schools, volunteer stores, lighthouses, &c., and Sunday schools and ragged schools, at the option of the rating authority. The London Hospital was exempt from rates by virtue of a local Act, the Whitechapel Act.

Before the committee adjourned they took some evidence from Mr. BURT, chairman of the Central Hospital Board, who supported the claim of the hospitals for exemption.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ABBOTT, T. E., L.S.A. Lond., has been appointed Vaccinator for the Registration District of Lyell, Tasmania.

ANDERSON, G. M., M.B., Ch.M. Aberd., has been appointed Vaccinator for the Health Districts of Franklin, South Franklin, and Port Cygnet, Tasmania.

ANDERSON, J. F., L.R.C.P., L.R.C.S. Edin., has been appointed Vaccinator for the Municipal District of Longford, Tasmania.

BLOMFIELD, A. B., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the North Peckham Sanitary District of the Parish of St. Giles, Camberwell, vice S. C. Phillips, deceased.

BUTCHART, J. E., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Vaccinator for the Municipal District of Oatlands, Tasmania.

CLARKE, A. H., L.R.C.P. Lond., M.R.C.S.., has been appointed Vaccinator for the Registration District of Hobart, and the towns of Bellerive and Beltana, Tasmania.

CLARKE, H. W., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Capel Sanitary District of the Dorking Union, vice J. L. Jardine, resigned.

Births, Marriages, and Deaths.

BIRTHS.

GOLDNEY.—On June 15th, at Richmond, Surrey, the wife of Thos. W. Goldney, M.R.C.S., of a daughter.

PROBYN-WILLIAMS.—On June 16th, at Welbeck-street, Cavendish-square, W., the wife of R. J. Probyn-Williams, M.D., of a son.

RUBEL.—On June 19th, at The Red House, River, near Dover, the wife of John L. Rubel, M.R.C.S., L.R.C.P., of a daughter.

SPRIGGE.—On June 19th, at Essex Villas, Kensington, the wife of S. Squire Sprigge, M.B., B.C. Cantab., of a daughter.

WARRINGTON.—On June 15th, at 69, Rodney-street, the wife of W. B. Warrington, M.D., M.R.C.P. Lond., of a daughter.

MARRIAGES.

BOND—IMRIE.—On June 16th, at Shortlands, Kent, Louisa, only daughter of the late Lancelot Dashwood, of Overstrand, Norfolk, and widow of the late Rev. T. Nairne Imrie, Rector of Holy Trinity, Dunfermline, Fife, to T. Bond, F.R.C.S., Consulting Surgeon to Westminster Hospital.

CORY—REEVE.—On June 12th, at the Parish Church, Tenterden, Charles George Cory, M.R.C.S., L.R.C.P., of Soham, Cambs, to Mabel Emily Hartridge Reeve, only child of the late Walter Reeve, Esq., of Peasmarsh, Sussex.

M'DONNELL—THOMPSON.—On June 15th, W. Campbell M'Donnell, M.R.C.S., L.R.C.P. Lond., 10, Park-lane, Stoke Newington, N., to Grace Thompson, L.O.S., lately of 23, Stoke Newington-road.

ROWLAND—TRUELL.—On June 14th, at the parish church, Wall, Lichfield, Frank Mortimer Rowland, M.D., B.A., of Lichfield, to Cornelia Isabel, second daughter of the Rev. W. H. A. Truell, Vicar of Wall.

STUART—DUTTON.—On June 14th, at St. Bartholomew's, Sydenham, Walter Lea Stuart, M.R.C.S., L.R.C.P. Lond., sixth surviving son of the late J. E. Stuart, of Fairview, Hampstead, to Katharine Eleanor, younger daughter of the late Rev. A. Dutton, formerly Vicar of West Hyde, Rickmansworth, Herts.

WOODHOUSE—NELSON.—On June 13th, at Esher Parish Church, Cecil Woodhouse, M.B., B.C. Cantab., of Homeside, Esher, to Norah Nelson, widow of the late Edward A. Nelson, and only daughter of Grinham Keen, Chadworth Cottage, Esher.

DEATHS.

ARGLES.—On June 14th, at Oxford-terrace, Hyde-park, W., suddenly, Robert Argles, L.R.C.P., aged 60.

BRYANT.—On June 7th, at Bloemfontein, South Africa, Hugh A. Bryant, aged 33, M.R.C.S., L.R.C.P., Civil Surgeon, Royal Army Medical Corps, and late of Shaftesbury.

DAVIES.—On June 15th, at Springfontein, South Africa, Herbert Davies, M.B., Ch.B. Vict., a Surgeon of the Welsh Military Hospital, son of Henry Davies, Carus Lodge, near Lancaster.

EMBLETON.—On June 18th, at Swanage, of apoplexy, Dennis Cawood Embleton, M.D., M.R.C.S., L.R.C.P., of St. Wilfrids, Bournemouth, aged 46.

GILLSON.—On June 2nd, William Edward Gillson, L.R.C.P. Lond., M.R.C.S., of Huntingdon-street, Barnsbury, in his 42nd year.

JONES.—On June 18th, at Springfontein, South Africa, Professor Thomas Jones, F.R.C.S.

JOHNSON.—On June 17th, at Beaconsfield, Bucks, Francis Johnson, M.R.C.S., L.K.Q.C.P.I., aged 50 years.

NEWTON.—On June 20th, at Trevor Dene, Penarth, Georgina, the wife of Charles John Newton, Surgeon, age 48 years.

WHEATLEY.—On the 14th inst. at the Grange, Loughton, William Henry Wheatley, L.D.S. (Lond. and Glasgow), aged 46 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A SEVENTEENTH-CENTURY PHYSICIAN ON THE CONTAGIOUSNESS OF PHTHISIS.

To the Editors of THE LANCET.

SIRS,—I have been surprised to find among the many authors quoted on the subject of the question of the contagiousness of phthisis and its treatment by the open-air method almost no mention of an English physician, Richard Morton, M.D., sometime Fellow of the College of Physicians, who flourished in London at the end of the seventeenth century and a copy of the second English (posthumous) edition, dated 1720, of whose book entitled "Phthisiologia or a Treatise of Consumptions, wherein the Difference, Nature, Causes, Signs, and Cure of all sorts of Consumptions are explained," has been long in my possession. In the preface the Latin edition (1689 quoted in the *British Medical Journal* of June 16th by Dr. Osler) is said to be already scarce and an apology is made for issuing it in the vulgar tongue. In the second book wherein the author treats "of an original consumption of the Lungs, he says that is original "which from the very beginning depends on an ill Disposition and an Exulceration of the Lungs." Among the causes he gives "Sixthly, Also a foggy and thick Air, and that which is filled with the Smoak of Coals, does extremely promote a Consumption ..... by stuffing and weakning the Lungs, that serve for Respiration, which are the Seat and Theatre of this Distemper." "Ninthly. This Disease is also propagated by *Infection*. For this Distemper (as I have observed by frequent Experience) *like a Contagious Fever does infect those that lie with the sick Person with a certain Taint.*" With regard to prevention he remarks: "Let the patient enjoy an open, fresh, kindly Air, and such as is free from the Smoak of Coals which may not only cherish the animal Spirits and comfort the Nervous Parts, and consequently restore the weak appetite, but likewise procure Quiet (at least in some measure) to the Lungs. But" (and I commend this to the *extreme* advocates of the "open-air" system of cure) "there must be great Care taken that he does not get new Cold. For the Body being in such a manner filled with a Load of Humours, every new Catarrh or Cold tends to a Consumption, and from hence come all our Sorrows." In respect of prognosis again Dr. Morton states "a consumption that is *got by Infection* but especially whenever that *Infection* is derived from one that has an acute and malignant consumption is, when all other circumstances are alike, more difficult to cure and for the most part more acute and fatal than other Consumptions." And again: "A Consumption in the Autumn, or Winter, though it may be relieved by a careful Management and the convenient Use of Medicines, yet it can never be perfectly cured without the benefit of the Spring and of the approaching Sun. For as the vesciculous Substance of the Lungs is almost continually penetrated by the Air, and by the Decree of Nature is blown up in the farthest corners of it by the continual succession of new Air, that is driven in and out by Respiration, so the present State of the Air must necessarily be of very great Moment, seeing it may either hinder or promote the cure of this Distemper, as it is found to be wholesomely dry and warm, or unwholesome, by being cold and cloudy. So that the due Constitution of the Air contributes not only to the Preservation of the Lungs when they are out of order, but also to their cure, more than the most pompous Heap of Medicines, which cannot be conveyed into the Blood and the Part affected so continually or in the same quantity as the Air is. And therefore 'tis usually in vain to expect the Cure of a Consumption in the winter time, and in autumn, to wit, while the State of the Air being cold, thick, and moist, and consequently unwholesome, does continually promote the Distemper more than a Store even of the most proper Medicines can stop and check it, when the Edge of the most powerful Remedies is taken off and their Efficacy weakened in this manner by the extremely incommodious State of the Air."

"History 3. Mr. Luff, the son of that Reverend Divine which I have already mentioned, living in Milk-street, after he had married a Virgin that was consumptive (and, as I remember, dyed within a Year after She was married, with an universal Colliquation and the other symptoms of a fatal Consumption of the Lungs) a few Months after her Death fell into a consumption (as I judged) *by Contagion.* To which fatal Disease an Haemoptoë prepared the way with which he was suddenly taken at Exeter, and that in the Winter time, and he lost a great deal of Blood. But as soon as his spitting of blood was stopt by Phlebotomy, a Milk Diet, and Incrassating Medicines and he had recovered his strength in some measure, being dismist by his Country Physician, within a fortnight (which was much sooner than was fit), he came to London on Horseback, and presently sent for me. But alas! how much was he changed from what he was before! I found the poor Patient very Feverish, and always coughing, and extremely wasted with a Colliquation that was now begun, and troubled with a Streightness and Pains in his Breast. I found it to be a mixt Fever, partly Peripneumonick, from a new Inflammation of some of the Tubercles, partly putrid, from the purulency of other Glandules, which had begun so soon to be ulcerated. I judged the Distemper to be a very acute Consumption of the Lungs from a spitting of blood which *as it was contracted by Infection*, as it was rendered

more hasty and violent by his ill Government in his Journey and his return into our Air that is filled with the Smoak of Coals. The violence of the Pain and Fever requiring it, I presently ordered a Vein to be opened, but I took away but a little Blood, because of the Consumption and Colliquation that was upon him. Then I endeavoured at least to stave off this hasty Ruin for some time with temperate Juleps and Opiates and all sorts of convenient Pectoral Medicines, Blisters, and a due management in all things. But all these things were to no purpose; for within three or four weeks he departed this Life, with all the Symptoms of a very acute Consumption of the Lungs."

There can be no more definite statements as to the contagiousness of consumption and the advisability of its open-air treatment than those contained in the above extracts, and I trust, Sirs, that you will, for the credit of English medicine, assist me to restore to his well-deserved niche in the Temple of Fame this ancient worthy. His whole work, although, of course, including much that is archaic, and sometimes even to our ideas offensive, in the way of treatment, teems with useful suggestions and is full of learned observations, the fruit of his close study of older writers, particularly Hippocrates, and of careful clinical and pathological work on his own part.

I am, Sirs, yours faithfully,

WM. J. TOWNSEND BARKER, M.R.C.S. Eng., L.R.C.P. Lond., D.P.H. Cantab., L.S.A.,
Formerly Physicians' Assistant, Bristol General Hospital.

Fulham, S.W., June 18th, 1900.

A MEDICAL TRIBUTE TO GENERAL BADEN-POWELL.

A LEAMINGTON paper publishes some verses written by Mr. Montagu Lomax and headed "To B.-P." We quote a few stanzas.

Oom Paul he spake in council, all his bravest in a ring,
"We have laid our plans of conquest—who will capture Mafeking?"
And the wily Cronje answered, as he stroked his grizzled cheek,
"Just a clump of wooden shanties; I can take it in a week."

* * * * *

And day by day their guns belched forth a storm of shot and shell,
And night by night the peaceful sky was lit with fires of hell;
But you didn't seem to mind it, though *your* guns were only toys,
And you signall'd, "Arn't you coming? You can't frighten us with noise!"

Then they called a solemn conclave, bearded cheek and sullen brow,
And they said, "These *verdomm'd rooineks* should have given in by now";
And they penned a wrathful missive: "We concede an hour's grace
Surrender at discretion, or we blow you into space!"

But they little knew the spirit of the man to whom they spoke,
With his air of gay *bonhomie*, and his heart of British oak;
"I have mined the chief approaches," so you wrote politely back,
"Towns don't fall by being looked at—won't you try a front attack?"

* * * * *

And week by week, and month by month, the weary siege went on,
And pestilence and famine thinn'd your numbers one by one;
But you only sat the tighter, took a hole up in your belt,
And looked for help, so slow to come, across the burning veldt.

But you never failed in courage, never lost your cheery tone,
And when the days were darkest you ran the show alone,
For you plann'd bazaars and concerts, wrote them comic songs to sing,
Then sent out fresh despatches: "All well—at Mafeking."

* * * * *

And when the help, so long delayed, so longed for, came at last,
And the pulses of an Empire's heart were beating loud and fast,
Amid all the songs and tumult that made each bosom swell,
Was the note of deep thanksgiving, "All's well, thank God, all's well!"

* * * * *

There are leagues and leagues of banners, from every roof they wave,
The grand old flag of England you fought so well to save;
And from Sydney to Vancouver the rocking belfries ring
The fame of Baden-Powell and glorious Mafeking.

Leamington Spa, May 21st. MONTAGU LOMAX.

ACCIDENTAL VACCINATION OF A WOMAN BY HER CHILD.

To the Editors of THE LANCET.

SIRS,—The following case is, I think, worthy of notice. Four weeks ago I was sent for to see a woman supposed to be suffering from erysipelas. When I arrived there I found the submaxillary lymphatic glands enlarged and a slight swelling of the left cheek. The lower lip was also swollen and had a large and a small vesicle near the junction of skin and mucous membrane about its centre. About 10 days previously I had vaccinated her child, and I extracted from her the information that the baby had scratched her lip and that she had accidentally rubbed the vaccination pad with some discharge on it on her mouth whilst dressing it. Under the treatment of a mild antiseptic mouth wash, painting the enlarged glands with tincture of iodine, and the administration of an aperient mixture the symptoms subsided, leaving two small cicatrices.

I am, Sirs, yours faithfully,

A. R. HENCHLEY, L.R.C.P., L.R.C.S. Edin.,
L.F.P.S. Glasg.

Blagdon, near Bristol.

"DEATHS UNDER CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—The report in THE LANCET of June 9th at page 1656 shows that chloroform administered by the towel or Simpson's method to the same patient and by the same administrator on two occasions, varies absolutely in the result produced—one administration all but kills the patient by respiratory paralysis, the other answers perfectly and everything goes well. Here we have actually demonstrated the uncertainty of the towel or rule-of-thumb method. The cause is evidently the utter uncertainty of the dosage afforded.

I venture to submit that this report of these two administrations justifies another protest against this mode of administration and, indeed, against any mode which does not register the amount of chloroform used and also enable the administrator to know how much chloroform vapour is passing into each inspiration. These essential requistes cannot be claimed for any rule-of-thumb method. This has been clearly shown lately by letters which have appeared, and especially by those of Dr. James Edmunds, in recent numbers of THE LANCET.

I should not presume to engage in the discussion of this question of the administration of chloroform did I not do so from personal experience, and I confess that I have learnt much from this practical method of gaining knowledge and thus putting myself in the place of my patient. In fact, Sirs, I venture to think that all those who administer anæsthetics should have personal knowledge of its effect on themselves, and I have been not a little surprised to hear how learnedly some discourse on the subject without ever having experienced its effects. I have therefore administered it to myself and have had it administered to me by Dr. Edmunds with the Krohne inhaler on the method described by him in THE LANCET.

On each occasion full surgical anæsthesia was gradually and comfortably induced—without an iota of coughing, discomfort, or resistance, and without any after discomfort. On one of these occasions we were honoured by the presence of Dr. Alexander Haig and Dr. Stretch Dowse, and "pipe-smoking anæsthesia" was, I am informed, fully induced, yet the chloroform used from the graduated bottle was only 35 minims and the time of induction was seven minutes.

It would give me great pleasure at any meeting of medical men to submit myself to chloroform again in the same way for the purpose of a demonstration. I think, Sirs, you will agree with me that it is as desirable as it is imperative in the face of so many deaths occurring under chloroform that the important question of the safest mode of administration be at once calmly and quietly considered and discussed, and the best system be recognised and adopted by all anæsthetists. I should consider the sacrifice of my life a small matter to attain this object.

I am, Sirs, yours faithfully,

C. J. HARRIS, M.R.C.S. Eng., &c.

Kilburn Priory, N.W., June 14th, 1900.

Income Tax.—Our correspondent might make a return based on his own estimated income for the ensuing year; but no doubt the surveyor for the district, if the return were lower than that of his predecessor, would assess him on the average of the returns made for the past three years. We should try the first course.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.).

WEDNESDAY (27th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.)

THURSDAY (28th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.).

FRIDAY (29th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Lonpon Throat (2 P.M. and 6 P.M.).

SATURDAY (30th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (25th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. M. Morris: Consultation. (Skin.)

LONDON THROAT HOSPITAL (204, Gt. Portland-street, W.).—4.30 P.M. Diagnosis and Prognosis in Chronic Deafness. (Post-graduate Course.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. S. Edwards: Urinary Cases.

TUESDAY (26th).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. F. W. Mott: The Degeneration of the Neurone. (Croonian Lecture.) Lecture III. Syllabus:—The Chemistry of Degeneration.—The Marchi Method and its Chemical Explanation.—The Decomposition of Myelin in Degeneration.—The Production of Cholin in the Blood and Cerebro-spinal Fluid, especially in Relation to General Paralysis.—The Chemical and Physiological Properties of Cholin.—Degeneration and Auto-intoxication.—The Influence of Nucleo-proteid in the Cerebro-spinal Fluid in Rapid Wasting Diseases of the Brain.—Chronic Toxic Condition of the Blood, with especial reference to the Influence of Alcohol and Syphilis in the Production of General Paralysis and Tabes.—Some Facts concerning the Pathology of General Paralysis.—The Close Relationship of the Two Diseases Considered Etiologically and Pathologically.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. Sharkey: Consultation. (Medical.)

WEDNESDAY (27th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—5 P.M. Mr. W. A. Jacobson: Consultation. (Surgical.)

EVELINA HOSPITAL (Southwark-bridge-road, S.E.).—4.30 P.M. Mr. W. Edmunds: Clinical Demonstration of Selected Surgical Cases. (Post-graduate Course.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Fowler: Thoracic Aneurysm.

MASON UNIVERSITY COLLEGE, BIRMINGHAM (Medical Lecture Theatre of the College).—4 P.M. Dr. O. J. Kauffmann: The Commoner Neuroses of Childhood, their Pathology and Treatment. (Ingleby Lecture.)

THURSDAY (28th).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. F. W. Mott: The Degeneration of the Neurone. (Croonian Lecture.) Lecture IV. Syllabus:—Primary Degeneration.—The Arguments in Favour of General Paralysis being a Primary Degeneration with Secondary Inflammatory Changes.—Primary Degeneration may Affect the Afferent System as in Tabes, the Efferent System as in Amyotrophic Lateral Sclerosis, or both Afferent and Efferent Systems as in Combined Sclerosis.—Observations upon Multiple Polyneuritis due to Alcoholism.—The Effect of Stress in the Production of Degeneration.—The Important Influence of Heredity in Nervous Diseases.—The Influence of Alcohol, Syphilis, and Tuberculosis upon the Germinal Plasm, and the Effects upon the Offspring in the Production of (*a*) Premature Decay of the Neurone, (*b*) Arrest of Development of the Neurone.—Juvenile General Paralysis Studied in 30 Cases.—Congenital Imbecility and Epilepsy from 40 Cases.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

LONDON SKIN HOSPITAL (40, Fitzroy-square, W.).—4 P.M. Mr. J. Startin: Interesting Clinical Cases (illustrations by lantern slides).

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. S. Edwards: Urinary Cases.

CHARING-CROSS HOSPITAL.—4 P.M. Dr. W. Hunter: Pathological Demonstration. (Post-graduate Course.)

FRIDAY (29th).—MEDICAL GRADUATES COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. D. Grant: Consultation. (Ear.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		FOR THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Miss A. S. Althaus, Lond.; Messrs. Allen and Hanburys, Lond.

B.—Mr. C. Birchall, Liverpool; T. B. Browne, Ltd., Lond.; Dr. J. Bissell, Ahmednagar, India; Mr. A. E. Barker, Lond.; Dr. James Burnet, Edinburgh; Mr. J. Townshend Barker, Lond.; Mr. A. A. Bradburne, Farnborough; *British and Colonial Druggist*, Editor of; Birmingham City Hospital, Medical Superintendent of; Mr. J. H. Broscomb, Birmingham; Bristol Royal Hospital for Sick Children, Secretary of.

C.—Mr. H. A. Collins, Saxmundham; Messrs. Cadett and Neall, Ashtead; Cornwall County Asylum, Bodmin, Secretary of; Messrs. Crossley and Co., Lond.; Cardiff Infirmary, Secretary of; Messrs. J. and A. Churchill, Lond.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Croonian Lectures

ON

THE DEGENERATION OF THE NEURONE.

Delivered before the Royal College of Physicians of London on June 19th, 21st, 26th, and 28th, 1900,

BY FREDERICK W. MOTT, M.D. LOND., F.R.S.,

PATHOLOGIST TO THE LONDON COUNTY ASYLUMS; PHYSICIAN-IN-CHARGE OF OUT-PATIENTS, CHARING-CROSS HOSPITAL.

LECTURE II.[1]

Delivered on June 21st, 1900.

MR. PRESIDENT AND GENTLEMEN,—In my last lecture I briefly referred to the present position of the neurone theory. I gave some examples of its practical application and I dwelt at some length upon a method which has been used for studying the bio-chemical changes which occur in the protoplasm of the nerve-cell. Moreover, I pointed out the important evidence afforded by the development of the myelin sheath in proving correlation of structure and function, and that the formation of myelin depends upon three fundamental biological principles: 1. An acquired inherent tendency the result of evolutional differentiation of structure and function, for certain systems, groups, and communities of neurones at successive periods of time to ensheathe their axis-cylinders with an insulating and protecting structure—the myelin sheath which in the case of the peripheral nerves is contained within and partially formed by a chain of tubular mesoblastic cells. 2. Phylogenetically and ontogenetically stimulus from without is the determining factor in the bio-chemical change associated with the deposition of myelin. 3. Absence of stimulus as occurs from long disuse occasions a regressive metamorphosis back to the embryonic type.

THE EFFECTS OF INJURY OF THE NEURONE.

Section of the axis-cylinder or destruction of the nerve-cell (speaking collectively), whether produced by direct trauma or by morbid processes occurring in the vascular and supporting structures of the nervous system, causes a simultaneous death-change of a characteristic chemical nature affecting the myelin sheath and axon extending from the point of injury to its terminal fibrils. This is Wallerian degeneration, or secondary degeneration of Waller and Türck. Ranvier showed that the sheath of Schwann consists of a series of tubular mesoblastic cells wrapped round the axon and that when a nerve is cut there is degeneration of the myelin and axon above the lesion as far as the next node. Each internode, therefore, represents a cell, and the fact that the degeneration does not extend upwards beyond the node allows the presumption that these tubular cells have some metabolic interaction with the contained axon and its surrounding myelin. But whatever that reciprocal metabolic interaction of the axon and its ensheathing structures may be, secondary Wallerian degeneration conclusively proves that it is controlled and determined by the nerve-cell and its contained nucleus; indeed, it is possible to conceive that the metabolic activity of the nucleus is the mainspring of this trophic influence, by the production of some bio-chemical or bio-physical stimulus which pervades the whole complex neurone even to its far distant prolongations. The Nissl method has shown that section of an axon causes changes in the nucleus and cell protoplasm. These may be temporary and recoverable or permanent and irrecoverable. The result apparently depends very much upon the degree and extent of the injury. When a peripheral nerve-fibre is cut through the trophic influence of the cell is removed from the axon and myelin sheath which it generated. These die; not so, however, the independent tubular cells of the sheath of Schwann, for these, soon after the death-change has commenced in the myelin, show signs of active proliferation. Whether, as some authorities would have us believe, they can lead to regeneration of the nerve, or whether, as seems much more probable, they prepare the way for the down-growing axon, I shall not here enter into, but that they have an important function in regeneration is undoubted, seeing that regeneration in the central nervous system, where the sheath of Schwann is absent, does not occur. Tuckett has shown that when a non-medullated sympathetic nerve is cut the nuclei and sheath-like structures remain unaltered, while the axon alone degenerates; it could thus appear that the degenerating myelin may act as a formative stimulus causing nuclear mitosis and cellular proliferation.

THE EFFECTS OF INJURY OF A NERVE UPON THE CELLS OF ORIGIN.

Only since the introduction of the Nissl method of staining has it become known that changes occur in the ganglion cells almost immediately after section of the nerve. Nissl, who first studied this, called it "*primäre Reizung*"; and Marinesco, who has made a special study of this subject, has shown that section of the hypoglossal nerve on one side is followed by three stages of change in the corresponding nucleus of origin. The hypoglossal nucleus is especially favourable for the study of this question, the nerve being purely motor. From the close proximity of the two nuclei comparative observations of the nuclei of the two sides make very evident changes, which occur as the result of section of the nerve on one side.

Marinesco divides these changes which occur in the nucleus into three phases. The *reaction* phase occurs during the first month and is characterised by a dissolution of the chromatophil elements and a displacement of the nucleus towards the periphery of the cell. This change has also been recognised by many other observers—namely, Nissl, Ballet et Dutil, Lugaro, Flatau, van Gehuchten, Sano, Erlanger, and others. The condition is not necessarily one of degeneration, as I shall show later. It is important to bear this in mind, for a similar condition may be found affecting the anterior horn cells in peripheral neuritis, where disease has led to a destruction of the axis-cylinder process. In the *reparation* phase the cell body increases in volume, the nucleus resumes its original position, and the cell shows a distinct pyknomorphic condition (abundance of stainable substance). About 90 days after the injury the process of reparation has proceeded so far that the nuclear group of the injured side is only distinguished from the uninjured side by the increase in size of the cells and their processes. A little later the cells return to their normal appearance, in point of time corresponding to the regeneration of the nerve. We may consider this cell-hypertrophy as

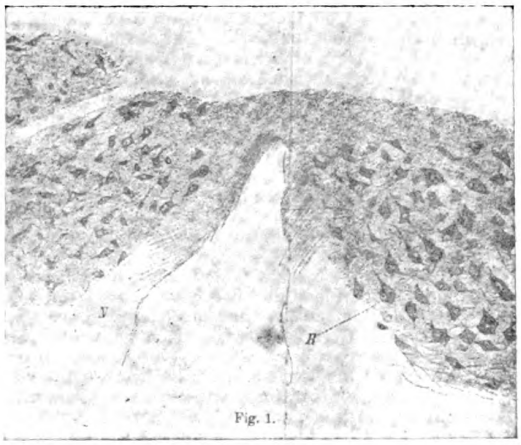

Fig. 1.

Hypoglossal nuclei of two sides. R indicates the swollen cells of the nucleus on the side of section during the phase of reparation. N indicates the normal side. (After Marinesco.)

evidence of the increased physiological activity necessary for regeneration. If now the hypoglossal nerve be torn out according to the method of von Gudden, or if a large piece of the nerve be resected, or any other condition arise so severe that the regeneration process in the nerve is prevented, then the reaction phase proceeds rapidly, and instead of a reparation phase of hypertrophy the cells undergo atrophy and a *degenerative* phase ensues. The accompanying diagram shows the changes in the cells of the hypoglossal

[1] Lecture I. was published in THE LANCET of June 23rd, 1900, p. 1779.

nucleus which result from section of the nerve in which regeneration is possible; it differs from tearing out the hypoglossal nerve in which regeneration is impossible. In the former case the return of the cells to normal is coincident with regeneration and return of function; in the latter the degeneration and subsequent atrophy of the cell group are brought about by such an injury as to render repair impossible and resembles therefore the effects of amputation of a limb. Recently Schäfer has shown that hemi-section of the spinal cord produces chromolytic changes in the cells of Clarke's column and subsequent atrophy, substantiating thereby the theory that these cells give origin to the dorsal and ventral cerebellar tracts, and Lloyd, a pupil of his, has also shown that the cells of Deiter's nucleus undergo similar changes, thus tending to support the observations of Risien Russell, Ferrier, and Turner, that the cells of this nucleus give origin to descending fibres in the antero-lateral region. We can thus see that this method has proved of the greatest value in determining the cells of origin of tracts of fibres. Some observers, Bregmann and Darkschewitz, have even found, after tearing out cranial nerves, a degeneration recognisable by the Marchi method and demonstrating the course of the nerve in the medulla or pons by the black-stained myelin. By the kindness of Mr. Victor Horsley I have the opportunity of exhibiting a lantern slide of the medulla showing degeneration back to the nucleus after an injury made just at the point of emergence of the nerve.

Marinesco, in his admirable work on the effects of amputation, describes slow progressive changes in the myelin sheath and says the normal refraction of the fat disappears, the colour reaction of the same tends to disappear, and following the changes in the myelin there is a change in the axis-cylinder. In addition, there appears a considerable nuclear proliferation of the sheath when the myelin has disappeared, the atrophied fibres bearing resemblance to non-medullated fibres. A recent observation by Noll, which I shall refer to later, showed that the protagon diminished in the central stump of a nerve after section, though, of course, not to such an extent as in the peripheral.

Barker, after referring to the above experiments, as well as to the studies of von Gudden and his pupils and the observations upon the nervous system following amputations, remarks: "We have seen that these observations have, partially at least, annulled the validity of Waller's doctrine of the trophic relations of the nerve cells, for after injury to an axon, in addition to the degeneration in the axon, peripheral to the lesion there are demonstrable alterations into the cyto-proximal end of the axon, and especially in the cell body of the neurone itself." The changes which occur after the amputation of limbs are probably, however, due to regressive atrophy from lack of stimulus from the structures over which the neurones presided. The changes which occur in the cells of origin of a nerve after section undoubtedly prove that the whole neurone has suffered by the injury, but there is no evidence to show that a degeneration occurs (in the sense of the chemical change to be referred to later), except in the peripheral portions of the cut nerve and in the central portion as far up as the next node of Ranvier, unless the injury is so severe as to cause such a shock to the neurone that it dies as a whole.

DISEASES OF THE NERVOUS SYSTEM AS DISTINGUISHED FROM DISEASES WITHIN THE NERVOUS SYSTEM.

The histological elements which make up the nervous system may be divided into two groups: (1) the nervous units or neurones; and (2) the supporting, protecting, and nutrient tissues. Organic diseases may start in a primary degeneration of the nervous units or neurones, or the neurones may be affected secondarily by diseases starting in the supporting, protecting, and nutrient tissues. Such are essentially diseases *within* the nervous system and include diseases of the blood-vessels, lymphatics, membranes, and special nerve connective tissue (neuroglia). These give rise to secondary degeneration, either by direct injury, inflammatory compression, or by cutting off the blood-supply.

The causes of pathological processes occurring in the nervous system may be considered under two headings—(1) external, and (2) internal; but it may be remarked that in all cases except direct injury the two groups are more or less combined. The external causes depend upon the condition of the blood and lymph by which the neurones are nourished and the excess or deficiency of normal stimulation or existence of abnormal stimulation. The internal causes depend upon the inherent vitality of the neurones themselves. In considering, therefore, the causes of degeneration of the neurone it will be necessary to point out the result of (1) failure of the blood-supply; (2) toxic conditions of the blood; (3) the effect of excess or deficiency of stimulation; and (4) inherited defects in the nervous system as a whole or in some particular groups or systems of neurones. To do this, however, in a satisfactory manner would necessitate my referring in a very superficial manner to all the diseases affecting the nervous system. I shall therefore limit myself especially to personal observations relating to some few causes of the degeneration of the neurone in each of those groups which I have studied.

Degeneration of the neurone may be studied by changes in (1) the nerve cell and (2) the axon and its sheath. By the neurone theory degeneration of the former must be associated with changes in the latter. We have also reasons for believing that degeneration primarily affecting the axon and its sheath must be associated with functional, if not degenerative, changes in the trophic and genetic centre of the nerve cell.

EFFECTS OF TEMPORARY OR PERMANENT FAILURE OF THE BLOOD-SUPPLY UPON THE NEURONE.

The effects produced by complete anæmia for varying periods of time upon the nervous elements of the spinal cord have been the subject of numerous experimental inquiries, but I am unaware of any systematic series of observations upon the effects produced by ligation of the cerebral arteries. Many clinical facts show that this is a subject worthy of attention, for the sudden loss of consciousness which results from syncope is explained by a failure of activity on the part of the nervous elements of the cortex cerebri, in consequence of default in the circulation in the hemispheres. Again, the sudden loss of consciousness in epilepsy, followed immediately by tonic spasms and then clonic spasms, has recently found a possible explanation in the series of very valuable experimental observations by Dr. Leonard Hill. He has found that artificial cerebral anæmia in cats or monkeys produced by ligation of the four cerebral arteries produces tonic spasm. If absinthe be injected, instead of causing clonic spasm it increases the tonic spasm. Then, if the clamp or ligature be loosened on a carotid so that blood flows back to the hemisphere clonic spasms almost immediately occur. This will again give place to tonic spasm on closing the artery; and again on removing the clamp, allowing the blood to flow to the hemisphere, the clonic spasms supervene. He has, moreover, shown that if all four arteries in an animal be ligatured, in the dog recovery takes place; the explanation is that collateral circulation is restored soon enough to prevent destructive changes occurring in the nervous elements. With two carotids and two vertebrals tied the dogs are for some days paretic and demented—very much in the condition of the dogs which Goltz showed after having removed the cerebral hemispheres; however, as Sir Astley Cooper and other observers have shown, these animals recover completely. Dr. Hill has been good enough to send me portions of the brains of 12 such animals operated upon, which after ligation of the four arteries were allowed to live for varying periods of time. I have examined the nervous elements with a view of determining the condition of the nerve-cells when the dog is in a state of paresis and dementia and when it has recovered so completely as to pass for a normal animal. The methods which I have adopted have been for this and all other experiments and observations referred to—the Nissl method, the Marchi, the Marchi-Pal, and rapid Golgi methods of staining. The changes observed in the brain by the Nissl method are shown in the accompanying photo-micrographs of the sections. (*Vide* Figs. 2, 4, and 5.) Before, however, speaking of the pathological changes I will again call your attention to the appearances of the pyramidal cells of the cortex, medulla, and spinal cord of a normal animal when examined by this method, for it is the most reliable we have at present for studying pathological changes by comparing the appearances presented with the normal cells. (*Vide* Figs. 1 and 3.) You will observe that, first of all, the cells have changed their shape; they are swollen up, their edges have not straight or incurved sides, but are curved outwards; the nuclei are swollen and often eccentric, and in some few of the cells may actually be extruded. When this has happened of course the cell has practically been destroyed and with it the nerve-fibre which contains its axis-cylinder projection. Another obvious sign of change, although not necessarily a destructive change, is the appearance presented by the chromophilous substance. It no longer presents those

definite figures which have received the name of Nissl bodies. Sometimes it appears as a fine dust, sometimes arranged in long threads separated from one another. One of the earliest changes to be observed is the absence or diminution of the chromophilous substance of the dendrons; moreover, the edges of the cells and the processes present a ragged instead of a clear-cut outline. Generally speaking, the changes in the chromophilous substance only do not denote destruction, but should the swelling be so great as to produce an extrusion of the nucleus the cell must necessarily die; and we can, if the animal be kept alive over 10 days, determine how many psycho-motor cells have been destroyed by the temporary anæmia occasioned by the ligation of the arteries. We can do this by examining sections of the pons, medulla, and spinal cord by the Marchi method. The number of black degenerated fibres will indicate the number of pyramidal motor neurones which have perished as a result of the anæmia. These are usually comparatively few. We may consequently say that mere swelling of the cells with very marked chromolytic changes does not mean more than functional disturbance. Mere hydration—for thus I explain the swelling—without dislocation of the nucleus from the cell, even though the chromolytic changes are very intense, does not mean death of the neurone. This is an important fact in view of the association of pathological symptoms with changes in the nerve-cell. Such microscopical changes are for the most part illustrated in the Supplement by Figs. 2, 4, 5, and 12. I would add in connexion with this series of experiments that the tangential fibres were found in most cases intact in animals that had completely recovered. We must suppose, therefore, that collateral circulation in dogs is restored very shortly after ligation of four arteries. The experiments of Ehrlich and Brieger in 1884 proved that anæmia of the lower portion of the spinal cord could be produced by ligature of the abdominal aorta, and that if the circulation was cut off for not longer than from a quarter of an hour to three-quarters of an hour only a temporary paralysis of the hinder extremities resulted, but if for one hour permanent paralysis and destruction of the nervous elements were invariably the result. Numbers of other experimenters have produced anæmia of the lumbar spinal cord by this method; and Sarbo has given a full account of the changes which occur in the cells as a result of complete anæmia lasting for from one hour to one and a half hours after ligation. The changes which he describes as occurring in the motor cells of the spinal cord as the result of complete occlusion of the circulation coincide very closely with the changes which I shall describe in other animals, especially monkeys and cats, also in dogs, which have died as a result of ligation of cerebral arteries, and in which collateral circulation was not soon enough established to prevent destructive changes. Sarbo found that ligature of the aorta for one hour in the rabbit caused a cell degeneration which was manifested by a granular destruction of the stainable substance of the cell protoplasm and a progressive homogeneous atrophic process affecting the cell nucleus. The appearances presented by the degenerating cells depended upon the time which was allowed to elapse between the ligation of the aorta and the killing of the animal—the longer the time the more evident was the cell destruction. He found no vascular changes indicating inflammations and no hæmorrhages.

The subject of cerebral anæmia is of clinical importance, as it is well known that in man ligature of a carotid for aneurysm has been followed by hemiplegia, and I have examined the brain in one such case. Dr. Hill sent me a piece of the cortex from similar situations in both hemispheres and asked me to decide by microscopical examination upon which side the patient was paralysed. This I correctly determined by the difference in the appearance of the cells of the two sides. We can understand, also, how *temporary* loss of motor or psychical function—e.g., transitory aphasia, monoplegia, hemiparesis, stupor, and dementia, or even hemiplegia—may occur in syphilitic disease of the arteries; for if collateral circulation be restored within an hour or so after the blocking of the artery, providing a thrombus does not spread to the small branches the circulation may be restored in the part and function may return in the course of a few hours or days.

In connexion with the experimental anæmia of the spinal cord produced by clamping the abdominal arteries it is of interest to note two points. The exogenous fibres of the posterior columns, together with the pyramidal tracts—tracts the fibres of which have their trophic and genetic centres respectively in the spinal ganglia and the cerebral cortex—do not undergo degeneration, whereas tracts which have for their trophic and genetic centres cells in the grey matter of the spinal cord undergo degeneration. Munzer and Wiener's experiments showed this, and recently I had the opportunity of examining a case of acute anterior poliomyelitis in an infant 14 days after the onset of the disease. In this case also the degeneration was limited entirely to those tracts the fibres of which arise from cells in the spinal cord, and I cannot help thinking that this case was of vascular origin—possibly spasm of the large artery which comes in to supply the lower end of the spinal cord. Ballet and Dutil found from their experiments that complete anæmia of the lower end of the spinal cord for a few minutes (by clamping the aorta) produced chromolytic changes in the anterior horn-cells. I have also found that swelling of the cells previously described, with chromolytic appearances, may come on within less than 10 minutes after ligation of the four cerebral arteries, for occasionally one of Dr. Hill's dogs or cats has died from the effect of the anæsthetic very shortly after the four arteries have been ligatured. It may be said that this was due to the anæsthetic. It was not, however, so, for occasionally I have had the opportunity of examining the brain tissues of animals which have died from the anæsthetic before any of the arteries were tied, and these showed no changes. (*Vide* Fig. 3, Supplement.) We may therefore consider that the changes noted are due to the cessation of the circulation. Dr. Hill has shown that the cortex of these animals is readily excitable, and in some cases even hyper-excitable to, electrical stimulations, epilepsy being produced. Consequently, this change in the appearance of the cells can be associated with increased electrical excitability, or, perhaps more likely increased tendency of stimulus to spread—a fact of considerable importance when put beside another fact—viz., that I have found in status epilepticus the cells presenting in many instances this swollen dropsical appearance, with marked changes in the chromo-philous substance. (*Vide* Fig. 13.) In general paralysis of the insane epileptiform seizures are of frequent occurrence, and when they do occur in the progress of the disease I have found invariably that in proportion to their frequency and severity there is a large number of recent degenerated fibres in the pyramidal systems. Consequently, we may assume that epileptiform seizures in this disease are associated with death of the cortical pyramidal motor neurones, due in some instances (I believe in great measure) to vascular disturbance of the cortex. (*Vide* Fig. 9.) The disease itself is, I consider, primarily a progressive decay of the nervous elements, but owing to the establishment of a vicious circle numbers of neurones are destroyed by circulatory disturbances.

I will now pass on to the effects of *experimental anæmia*, produced by ligature of arteries in which collateral circulation was not restored soon enough to prevent destructive changes in the nerve-cells. If cats or monkeys have all four arteries ligatured, or if, instead of ligaturing both vertebrals and both carotids in dogs, a subclavian be tied instead of one of the vertebrals, a sufficient collateral circulation cannot be restored soon enough and the animal dies in a period varying from a quarter of an hour to 24 hours. The time variation no doubt depends upon the effect produced upon the medulla by the anæmia. The changes observed in the cells of animals which have thus lived some hours are different entirely to those which have been previously described. There is not merely a physical change due to hydration; this may or may not be present, for sometimes the cells are not swollen, but are even shrunken. The staining reaction is also different, showing a bio-chemical as well as a biophysical change; sometimes the whole cell stains uniformly but not with a brilliant colouration. (*Vide* Fig. 7.) If a double stain has been used, for example, methyl-blue and saffranine, the whole cell may be stained a uniform dull purple, the processes, as well as the body of the cell, having a homogeneous instead of a differentiated reaction to the dyes—a condition which is similar to that met with in hyperpyrexia and to the appearances described by Sarbo in the motor-spinal neurones of the lumbar-sacral region after clamping the abdominal aorta. These animals prior to death, according to Dr. Hill's notes, generally had epileptiform convulsions. One animal, a monkey, presented the most instructive changes, because after ligature of both carotids and one vertebral it was paretic and demented, took no notice of anything, and behaved exactly like an

animal with its higher cortical centres destroyed, which indeed they were. It was killed on the fifth day and examination of the brain of this animal exhibited the following changes, which are shown in the accompanying photo-micrographs. The nerve-cells and all their processes were uniformly stained a diffuse dull purple and were readily discerned on account of the dilatation of the lymph space in which the neurone lies; scattered through the protoplasm of the cells was a fine dust of coloured particles; the apical processes of the cells were either destroyed or twisted like corkscrews; in many the dendrites had disappeared, but in some of the cells the axis-cylinder could be traced with unusual distinctness, probably due to some swelling; and one cell was observed which is of interest because the axis-cylinder process could be traced some distance, giving off lateral twigs that seemed to merge into a general network, supporting, therefore, the diffuse nerve network theory of Golgi. (*Vide* Fig. 6.) Many of the cells were swollen up, as Fig. 8 shows, and others were shrunken. Some could be seen with phagocytes sticking to them and devouring the dead cells. Although one observed these very marked changes in the cells by the Nissl and Weigert iron methods, yet by the chrome-silver method the cells appeared normal, showing the gemmules on their processes with unusual distinctness (*vide* photo-micrographs 10 and 11). The brains of other animals, dogs and cats, were examined by similar methods with the same results. It may be that the chrome silver only stained those cells which had not undergone disorganisation; but none of the cells when examined by the methods I have alluded to exhibited normal appearances as regards their bio-chemical condition nor was the animal physiologically normal. I have therefore come to the conclusion that the rapid silver method of Golgi which stains only a few cells, although undoubtedly of the greatest value for anatomical purposes, yet for acute pathological findings is unreliable. Many of the statements which are made with regard to the effects of drugs, anæsthetics, and acute disease, as represented by the appearances of the gemmules on the processes of the cells, as made evident by the chrome-silver method, are therefore open to serious objections. It is very probable that the method of Cox might be found of value in determining changes in the cells of the cortex in chronic disease and possibly also in acute disease. I have not mentioned that in most of these brains experimented on a striking naked-eye feature was the distension of the veins of the cortex with blood, and frequently there was sub-pial hæmorrhage; also the peri-vascular lymphatics were usually distended with fluid. No doubt, both the increase of blood in the superficial veins, the increase of fluid in the peri-vascular lymphatics, and the general œdema of the brain itself were proportional and compensatory to the diminution of the arterial blood. The arteries were generally empty, likewise the capillaries. In some cases the peri-vascular lymphatics and membranes were the seat of a marked cellular infiltration resembling the condition found in general paralysis. Collateral circulation to the medulla, by which the respiratory centre is kept going, is essential to life. Such collateral circulation when established—and if the animal lives it must have been established—would be accompanied by blood-supply to the choroid plexus, and the cerebro-spinal fluid, which functions as the lymph of the brain, would consequently be secreted in abundance and soon compensate for the diminution caused by the failure of the arterial circulation. Thus the increase of cerebro-spinal fluid would account for the œdema of the brain, the dropsical condition of the cells, and the dilatation of the peri-vascular lymphatics.

Some experiments which I made five years ago with Professor C. S. Sherrington, and which we have never found opportunity to continue and develop, are, I think, of sufficient importance to mention with this subject of anæmia. We found that compression of the spinal cord in the dorsal region, even enough to produce indentation, would not stop the passage of impulses generated by faradaic excitation of the cerebral cortex to the lower spinal motor neurones. In two animals—monkeys—upon compression with an eye removed from a rat immediately after death, fixed at the end of a glass tube attached to a horizontal lever in such a way that compression of the cord could be made by this living tissue and the pressure measured by means of a sliding weight, we found that *extremely light pressure* upon the lumbar spinal cord was sufficient to abolish conduction in from one minute to one and a half minutes after the pressure was applied, and upon removing the pressure conduction in a minute or two returned because faradaic excitation of the cortex was responded to by an appropriate muscular contraction. The experiment was repeated a considerable number of times and I have no doubt that in these two animals we managed to produce an anæmia of the grey matter of the lumbo-sacral spinal cord by compression of the large artery that comes in about the third lumbar root, causing a physiological block in the synapsis formed by the terminal arborisations of the axons of the cortical pyramidal neurones with the dendrons of the spinal motor neurones.

EFFECTS OF HÆMORRHAGE.

Large quantities of blood may be lost to the body from hæmorrhage without producing any appreciable changes in the nervous elements. Voss has performed a number of experiments on animals, endeavouring to produce degeneration of the spinal cord by injections of pyridine sufficient to produce a severe anæmia, but without result. Likewise, numbers of cases of pernicious anæmia, leucocythæmia, and exhausting blood disease are not found associated with any noticeable change in the neurones. I have examined the nervous system in several cases of pernicious anæmia (in one of which the corpuscles had sunk to 500,000 per cubic millimetre), in cases of very severe anæmia from hæmorrhage and exhausting disease, and leucocythæmia (in which the red corpuscles were reduced to one-fourth and in which the whole of the brain and vessels showed congestive stasis and hæmorrhages), and yet the nerve-cells of these cases of extreme anæmia showed little or no bio-chemical change, the Nissl granules appearing quite normal (*vide* Fig. 1). Nor did sections of the nervous system in these cases show any degenerative changes by the Marchi method. It is, therefore, more than probable that those cases of combined sclerosis of the spinal cord, sometimes met with in pernicious anæmia but more often accompanied by grave anæmia, are due to some other cause than the deficiency of red corpuscles. Probably in the blood there is some neuro-toxin which produces this primary systemic degeneration of neurones with long axis-cylinder projections, forming the long tracts in the spinal cord; or it possibly may be that those individuals who suffer from this nervous affection have an inherent defective vitality or lowered durability of the nervous system which, in combination with the defect of the blood-supply in quantity and quality, leads to degeneration. The fact that inanition, even extreme inanition, produces little or no loss of weight in the nervous system and hardly any changes of importance in the microscopical appearances of the nervous elements is of considerable importance, for it seems to show that the metabolic exchange which goes on in the nervous system is either especially protected by the metabolism of the whole body being subservient to it, or that however important the metabolic exchange in the nervous system may be, in amount it is not considerable. Those primary wasting diseases affecting systems, communities, and groups of neurones, associated one with another by functional relationship rather than by anatomical or vascular supply, insidious in origin and progressive in course, cannot be essentially due to anything else than a metabolic failure on the part of the neurones themselves (which, after all, are but complex differentiated cells) to assimilate from the blood the necessary materials to maintain their specific vital energy. They die in a manner the reverse of their evolution, the most distant parts of the tree—namely, the terminal twigs (collaterals)—being the first to go, then the branches, and last of all the trophic and genetic centre itself, the cell body and its nucleus.

Dr. Watson in my laboratory has carefully compared the sections of these experimental anæmic brains with a large number of sections of general paralysis. He has made drawings of cells which he considered presented similar appearances in the two conditions and the result of his observations appears to show that whilst a large number of the cells exhibit changes indicating chronic atrophy, a considerable number of cells in general paralysis present acute destructive changes similar to those met with in cases of experimental anæmia from arterial occlusion, but they are scattered about in small foci. Arteries in this disease are seldom occluded, whereas congestive stasis in the arterioles, capillaries, and veins, even thrombosis in the latter, is common; and we may consider that the destruction of the nervous tissue of the cortex may be accelerated by inflammatory stasis. It is curious how general it is to find the brain atrophy in this disease limited particularly to the

frontal and central convolutions, whereas the occipital and temporal lobes escape in great measure. Over the atrophied regions the pia-arachnoid membrane is thickened and adherent. Many observers, including Flechsig and Mickle, consider that the region of atrophy corresponds particularly with the area of distribution of the internal carotid arteries. I think, however, the area of atrophy and pia-arachnoid thickening more closely corresponds with the distribution of veins which open into the longitudinal sinus, and from a large number of observations made by myself and my assistants I have come to the conclusion that venous congestive stasis in that portion of the brain plays an important part in the symptomatology and pathology of general paralysis. I shall, however, have occasion to refer to this more fully later.

Mendel and many authorities believe that general paralysis is a primary inflammatory condition of the vessels and meninges with secondary destruction of the nervous elements. In 1884 Mendel, who believed that the necessary factors were (1) diseased walls of vessels allowing transudation of plasma and leucocytes, and (2) hyperæmia of the brain, claimed to have produced this condition artificially by rotating dogs upon a table with the heads outwards. Fürstner repeated these experiments over a considerable period of time, causing degenerative changes in the cortex, with secondary descending changes in the cord. There are many reasons, however, which will be alluded to later, for considering general paralysis to be a primary progressive decay of the nervous elements with secondary changes in the vessels and membranes.

ALTERED STATES OF THE BLOOD; HYPERPYREXIA.

The study of the lesions of nervous centres due to hyperpyrexia is of great interest from a theoretical as well as from a practical point of view—from the former because the exact knowledge of the nature of the lesion might be able to throw some light upon the nature of the pathological process and the clinical symptoms which accompany hyperpyrexia; from the latter because it would indicate the direction of treatment. Goldscheider and Flatau, who for the first time described lesions of the nerve cells in the rabbit caused by experimental hyperthermia, came to the following conclusions:—1. If the temperature remained about 106·7° F. the cells of the spinal cord examined by Nissl's method presented no appreciable modifications. 2. If the temperature exceeded 109·5° F. the lesions of the nerve-cells of the spinal cord were very definite, extending throughout the whole of the grey matter. 3. The duration of the experimental hyperthermia they showed to be a very important factor in the production of the lesions, for if the animal be kept for some hours between 107° and 108° F. the same effect on the nerve-cells is produced as occurs in a much more rapid manner when the temperature is raised to 109·5° F.—viz., swelling of the cell and its processes; diffuse staining of the whole neurone with disintegration of the chromophilous substance; and around the nucleus the chromophilous elements still persisting to some extent as if the outer portions of the cell were more affected than the central. The nucleus has an irregular and often an angular appearance.

Marinesco has also done some valuable work on this subject; he found that if artificial hyperthermia in animals be produced, so that the temperature is raised to 116·6° F. in the rectum, the animal died in 30 minutes with characteristic changes in the nerve-cells. He also remarked that these changes occur at a lower temperature when the duration is increased. In five cases of hyperpyrexia occurring in the human subject which I have examined, and in which the temperature reached 109° F. or more, I have found the same bio-chemical change revealed by the Nissl method in all the cells of the central nervous system. I have, however, met with cases of status epilepticus in which the temperature was from 107° to 107·5° F. for a short time without showing this change. Again, I have seen in one case a moderate degree of chromolysis and diffuse staining in prolonged pyrexia varying from 103° to 106·5° F. This was in a case of typhoid fever, and it might very well be that the change was due to the influence of the toxin. In fact, in most of the human cases the changes could be ascribed to the conditions which produced the fever and not to the influence of the increased temperature of the blood. Some of the cases which I have examined, however, were sudden—e.g., one was probable sunstroke, another was a case of hæmorrhage into the spinal canal and the base of the brain in general paralysis, and another was a case of Congo sickness. The photo-micrograph (Fig. 14) shows three anterior horn cells from the last case. You will observe the diffuse staining of the processes and of the body of the cell. Another case of Congo sickness in which the temperature never went above 103° F. showed no change in the Nissl granules and the cells presented a fairly normal appearance. I have examined the nerve-cells in many cases of septic poisoning and other diseases, but I have never seen this change unless there was either hyperpyrexia or prolonged high fever (*vide* Fig. 1, Supplement). The fact that experimental hyperthermia in animals produces this bio-chemical change in the protoplasm of the cell indicates that it is the altered temperature of the blood which is the cause in the human subject of these changes. Another point is that if the sections are stained with methylene blue and saffranine the protoplasm is stained a uniform dull purple instead of being differentiated. Now we have seen that the healthy cell shows a differentiation of staining; the Nissl granules which have been shown to be a nucleo-albumin are no longer visible in hyperpyrexia; and there is no longer the differentiation of a stainable and an unstainable substance with basic dyes. There must, therefore, have been produced by the fever a profound modification of the protoplasm of the cell. There are two points to be considered in this—viz.: (1) the fact that a temperature of 109·5° F. can bring about rapidly this coagulation process and death of the protoplasm, also that it affects first and most markedly the periphery of the cell; and (2) that prolonged high temperature of from 107° to 108° F. will produce this same coagulation process.

Halliburton has shown that there are three proteids in nervous matter—viz.: (1) a neuroglobulin which is coagulated at 116·6° F. (47° C.); (2) a nucleo-proteid which is coagulated at 132·8° F. (56° C.); and (3) a neuroglobulin which is precipitated at 167° F. (75° C.)—and that these three bodies can be separated out by fractional coagulation. We see, then, how it is that Marinesco found that animals in which the temperature is raised to 116·6° F. (47° C.) died almost immediately with changes in the cells indicating coagulation in the protoplasm. No doubt this neuroglobulin is precipitated at once, and it occurred to me that if a solution of neuroglobulin were subjected to long heating it would coagulate at a much lower temperature. I mentioned the matter to Dr. W. D. Halliburton who was of the same opinion, and we have therefore made experiments on this subject, and we find that prolonged heating for four hours, for example, will cause coagulation of the neuroglobulin at a temperature of between 107·6° and 109·4° F. (42° to 43° C.). Moreover, Dr. T. G. Brodie and Dr. Richardson have shown that in frog's muscle the tissue loses its irritability at that temperature at which coagulation is induced first in one of its constituent proteids. We have thus a chemical explanation of the cause of death of the protoplasm, also of the changes manifested by it as regards staining.

Goldscheider and Marinesco have shown experimentally that a certain degree of this coagulation change may take place without death of the cells; for if they produce artificially hyperthermia in animals for only a short time and then kill them they find a commencement of this coagulation process to have taken place. But these animals would have lived had they not been killed for the purpose of examination, consequently we may suppose that a certain degree of bio-chemical change, associated with coagulation of neuroglobulin, may take place without destroying the protoplasm to such a degree as to render it incapable of recovery. I think this entirely coincides with and explains the remission of symptoms, the return of consciousness, and the recovery which often takes place in some forms of hyperpyrexia when the cold bath method is resorted to without delay.

It is a matter of speculation whether structures later developed and functionally more highly differentiated, as the cells of the cerebral cortex, are more highly susceptible to fever and succumb more readily under it. Possibly high temperature of the surrounding blood and lymph is more readily felt by the small cells of the superficial layers of the cortex on account of the increased surface exposed and delirium followed by coma may be the result of this, although the vital centres in the medulla may still be able to perform their functions.

The diffuse staining of the cells indicates a diffusion of the nucleo-proteid through the substance of the cell body and its processes. We may suppose, therefore, that the

essential achromatic fibrillary substance is killed and that the nucleo-proteid which is normally contained in the reticulum of the cell in solution has soaked into the achromatic substance and given the protoplasm the uniform staining which, when once general, is quite characteristic of hyperpyrexial death, as I have been able to verify in several instances. These facts, pointing to an actual bio-chemical change involving the death of the protoplasm when the temperature remains for some hours above 109° F., support Dr. Osler's view that cases of paradoxical temperature occurring in women and termed "hysterical hyperpyrexia" are frauds as a rule, although he states that other cases have to be accepted, the explanation of which is impossible under known rules—in fact, it is quite conclusive that temperature above 114° F. is incompatible with life, even for a short time.

TOXIC CONDITIONS OF THE BLOOD AND LYMPH.

The primary degenerative changes occurring in the neurone are usually the result of poisonous conditions of the blood and lymph. The poisons may be produced: (1) within the body by perverted functions of the organs or tissues (auto-intoxication); (2) by the action of micro-organisms upon the living fluids and tissues of the body whereby various toxic substances are produced, either locally or generally, and by their escape into the blood cause degenerative changes; and (3) the poisonous substance may be introduced into the body from without. Just as we know that various alkaloids used in medicine have a specific affinity for particular portions of the nervous and muscular systems, so we find that certain poisons which produce degeneration and disease have a special selective influence. We know that strychnine, for example, has a special selective influence upon the spinal cord, increasing reflex excitability. Goldscheider and Flatau have shown that strychnine poisoning produces changes in the motor anterior horn cells closely corresponding to those observed in tetanus poisoning; these changes may be observed as commencing three minutes after injection of the poison if a sufficient dose be given. As in tetanus poisoning there is no close relationship between the morphological change and the degree of functional disturbance. These observers have also shown that acute cell changes occur as a result of malonitril poisoning ($NC—CH_2—CN$). Injection of hyposulphite of soda neutralises the toxic effects of this poison and prevents the changes in the nerve-cells. Experiment has shown that curare poisons the motor end plates, and recently, in an interesting communication, Dr. Augustus Waller showed how a very slight difference—a molecule of water—will alter the action of an alkaloid. Thus he has shown that veratrin has a special selective toxic action upon muscle, while proto-veratrin acts upon nerve. These facts, together with others which I will cite in connexion with degenerative changes produced by the selective action of poisons in the production of disease, indicate a special chemical affinity of certain protoplasmic structures for certain particular poisons; and the corollary is that probably the protoplasm of every nerve structure having a different function varies to some slight degree. There is a difference which is not to be detected by chemical methods, but the varieties of which are clearly shown by the difference in their physiological reaction to an altered environment. Perhaps one of the most striking demonstrations of this selective affinity of protoplasm for particular chemical compounds is shown by the intra-vitam methylene blue method introduced by Professor Ehrlich, and which in the hands of many investigators has produced such marvellous revelations into the minute structure of the nervous system. Ehrlich found that only those aniline dyes which contained sulphur in their composition were suitable for yielding the reaction. Examples of the special selective influence of the various poisons which produce disease are very numerous. There is a whole class of poisons which affect especially the peripheral nerves; and it is a debateable point whether in peripheral neuritis the whole neurone suffers, or whether the changes which have been found in the cells of origin of the peripheral nerves and in the spinal cord and ganglia are due primarily to the action of poison or whether they are secondary to the destructive effects of the poison upon the outgrowths of the cells—viz., the axis-cylinder processes of the peripheral nerves. Again, there are a number of poisons—diphtheria, botulismus, &c.—in which the fatty degeneration of the muscle is far in excess of what could be reasonably attributed to the changes found in the nerves. Probably the vulnerable point of the neuro-muscular mechanism is at the junction of the nerve with the muscle. Comparative studies, however, which would show degenerative changes in the motor end plates are extremely difficult, and it is rather by inference than direct observation that we must believe the poison to act upon this structure.

The effects of a poison in producing degenerative changes may be immediate or remote, even distantly remote. Thus some poisons on entering the system may produce sudden, or almost sudden, effects—viz., strychnine or absinthe. Others produce more or less remote effects—viz., rabies, tetanus, or diphtheria; others produce distantly remote effects, as syphilis.

Again, many poisons in order to be effective must accumulate in the system—viz., the mineral poisons, lead, and arsenic. Dixon Mann states that it has been shown that lead exists in the brain in appreciable quantities in encephalitis saturnina.

SELECTIVE INFLUENCE OF POISONS.

The most remarkable example of selective influence which I can cite is tetanus. The bacilli are found only in the wound—they must, therefore, be comparatively few in number, yet they elaborate a virulent poison which affects particular groups of neurones. The fact that lockjaw in man nearly always occurs first shows that the poison selects the motor nucleus of the fifth nerve. This, however, is not the case in animals when poisoned by the tetanus toxin. We do not know whether this selection is due to some anatomical condition which favours the absorption of the poison or whether it is the result of a bio-chemical affinity of that particular group of neurones for the poison. It is remarkable that experiment has shown that the tetanus toxin if mixed with an emulsion of nervous matter before injection into an animal loses its toxicity, showing thereby its affinity for nervous matter. Goldscheider and Flatau, who have studied the changes in the nerve-cells of animals that have been injected with the tetanus toxin, describe conditions which they consider characteristic of the action of this particular poison. Examination of the cells of the anterior horns of the spinal cord shows enlargement and pallor of the nucleus, swelling and crumbling of the Nissl bodies, and fine granular disintegration of the Nissl bodies associated with swelling of the whole cell.

Marinesco maintains that in nerve-cells subjected to the action of the tetanus toxin two independent phenomena can be distinguished, one the result of the chemical combination of the poison with the cellular protoplasm and the other the wearing out of the cell from excessive functional activity. He agrees with the conclusion of Goldscheider that there is a chemical transformation exalting the excitability of the motor neurones. There is a general consensus of opinion among authors who have worked at this subject, including those named, that the injection of tetanus antitoxin retarded these cell changes and caused a more rapid return to normal. It is only right to say that Courmon, Doyen, and Pairot, from experimental results of their own, deny that tetanus toxin produces any alteration in the cells of the anterior horns, and certainly specimens of the medulla and pons from two cases of tetanus in the human subject which I have had the opportunity of examining showed no certain noteworthy change.

Another poison, probably of microbial origin, rabies, has a special selective influence upon the medulla, although the whole nervous system is charged with the poison, pointing, therefore, to the fact that there is some special affinity of the neurones in the medulla for the poison. I have had the opportunity (through the kindness of Dr. Herbert Durham) of examining the medulla of a child who died from hydrophobia in Guy's Hospital six weeks after having been bitten by a mad dog. The greater number of the cells of the motor nuclei of the medulla showed marked degenerative changes, indicating a slow process of coagulation necrosis—viz., uniform diffuse staining with absence of Nissl granules; there was also a great deal of nuclear proliferation in the glia substance, denoting an irritative as well as a degenerative process. Dr. Herbert Durham was also kind enough to give me the nervous systems of three animals which had been poisoned with the toxin of "bacillus botulinus"—first described by Ermenghen who discovered the organism in unsound meat and fish eaten by people who had died with a characteristic group of symptoms. Such a condition in this country would probably have been called "ptomaine poisoning." The changes which I have

found in the nerve-cells are similar to those described by Marinesco who has specially studied this subject. There is a marked chromolytic change, some cells being much more affected than others (*vide* photo-micrograph, Fig. 16). The poison is extremely virulent and if a minute dose is given so that the animal does not die before the end of a week or so the changes in the nerve-cells are not more marked than in an animal which dies within 24 hours. The most noteworthy change, however, which I have found in an animal which survived eight days was the extreme fatty degeneration of the heart and striped muscles of the body (*vide* photo-micrograph, Fig. 17). The liver also had undergone extreme fatty degeneration. Seeing that the peripheral nerves showed no degenerative changes one may conclude that the poison acted more particularly upon the muscle or the nerve endings in muscle. As I have already had occasion to point out chromolytic changes of themselves do not indicate death of the nerve-cell but rather functional depression. Seeing that there were no changes in the peripheral nerves or in the cord observable by the Marchi method it is probable that the changes in the nerve-cells were mostly related to functional depression rather than actual destruction, and might have arisen from circulatory failure in the central nervous system due to paralysis of the heart. Marinesco noticed that the chromatolysis generally occurred first at the periphery of the cells; as the morbid process advanced there was destruction of the achromatic fibrils and formation of vacuoles. I have not observed vacuolisation, only extreme chromatolysis. Kempner and Pollak have found similar changes in the nerve-cells, and have further observed the slow restoration of the cells to normal under the action of specific antitoxin. Somewhat similar changes have been described by several authorities in the anterior horn-cells of the spinal cord and medulla of animals injected with diphtheria toxin. Dr. Sidney Martin separated the chemical toxin of diphtheria and produced by its injection into animals marked fatty degeneration of the muscles which he attributed to an associated change in the nerves. In four cases of diphtheritic paralysis in man which I have examined I was able to find fatty degeneration of the heart muscle in all; in only one case could I find Wallerian degeneration of the peripheral nerves, and in only this one case could I find any chromolytic changes in the motor-cells of the medulla.

Abrin and ricin-toxic proteid bodies.—Dr. Sidney Martin long ago showed that the seeds of jequirity contained a proteid body which if injected into an animal profoundly modified the blood and caused its death. This body, abrin, together with a similar body, ricin, obtained from castor-oil seeds, were made the subject of a most valuable research by Ehrlich. Very small quantities of these poisons injected into animals cause profound modifications in the appearance of the nerve-cells. The Nissl bodies disappear, the cells are stained uniformly, and show a fine-coloured dust all through the protoplasm of the cell and processes. All the nerve-cells are affected, and the cause of these altered appearances would indicate a changed condition of the blood and lymph rather than a selective influence of the cells for the poison. I have examined the nervous systems of two guinea-pigs which Dr. Durham kindly sent me. One animal died 45 hours after the injection of 0·2 milligramme of abrin globulin and all the cells showed the appearances described (*vide* photo-micrograph, Fig. 15). The other animal had been immunised and then in the course of a week received an amount equal to 60 fatal doses without succumbing; the nervous structures in this animal showed far less change—most of the cells exhibited Nissl granules although many showed more or less advanced chromolysis. Berkeley has studied the changes produced in the nerve-cells by ricin.

Absinthe.—Dr. Leonard Hill, while making his experiments upon the cerebral circulation, had occasion to inject animals with absinthe. He sent me the nervous tissues of these animals and I was greatly surprised to find that changes were discoverable in the cortical pyramidal cells of animals which had died in fits within 10 minutes of the injection of five minims of the poison. The cells were, however, not all equally affected, some groups of cells showed marked chromolytic change, while others showed no change. Animals that had lived two hours after the injection of a smaller dose (two minims) likewise showed unequal effects.

The cortical pyramidal cells were, however, always more affected than the motor cells of the anterior horns of the medulla and spinal cord; and one therefore naturally asks, Can we account for this by supposing that the cells have each a specific vital resistance? That this may be so is perfectly clear from the fact that such poisons as abrin, botulin, ricin, &c., produce when injected much more marked effects on some cells of the same function than on others. In the case of absinthe it must be remembered that we have to do with an oily fluid, and it is possible that really the fits may have been due to irritation caused by minute capillary emboli of an acrid and poisonous nature becoming lodged in the minute vessels of the cerebral cortex. The capillaries in the cortex are extremely small and would favour such lodgment. Such an explanation seems possible, for if absinthe be injected subcutaneously, even in large quantities, fits are not produced (Hill). I am also indebted to Mr. Victor Horsley for the nervous system of a cat which had received two minims of absinthe intravenously injected. The animal had three fits and survived two hours. The changes in the motor cells of the brain and cord corresponded to those above described.

DESCRIPTION OF PHOTO-MICROGRAPHS OF SUPPLEMENT.

1. Normal pyramidal Bett's cell, cortex cerebri, stained by the Nissl method. The preparation was made from the brain of a man who died from an obscure septic affection after eight weeks' illness. Towards the end of life he suffered from severe hæmorrhages, producing the most extreme anæmia, the blood containing a large number of nucleated corpuscles. There was a remittent pyrexia during the whole period; the fever, however, never surmounted 103·5° F. The body was extremely emaciated at death. He remained conscious to the end, and it is interesting that this combination of factors was insufficient to produce bio-chemical changes in the nerve cells. Magnification 700 diameters.

2. Section of the cortex cerebri of a dog after ligation of both carotids and both vertebrals. Magnification 250 diameters.

3. Section of the cortex of a cat that died under the influence of an anæsthetic prior to ligation of arteries. Normal appearance of the cortical pyramidal cells stained by the Nissl method. Magnification 300 diameters.

4. Pyramidal cell of a dog after ligation of two carotids, one vertebral and one subclavian. Great swelling of the nucleus, advanced chromatolysis most marked at the periphery of the cell. Magnification 700 diameters.

5. Pyramidal cell of a dog after ligation of arteries, showing extreme chromatolysis with commencing extrusion of the nucleus. Magnification 700 diameters.

6. Axis-cylinder process from a large pyramidal cell, the lymph space around which is distended, and showing the collateral side branches apparently forming a diffuse nerve network. Magnification 1000 diameters.

7. Pyramidal cell with diffuse staining from a cat after ligation of four cerebral arteries. Magnification 500 diameters.

8. Pyramidal cell from a monkey five days after ligature of two carotids and one vertebral, showing swelling in the pyramidal cell with diffuse homogeneous staining owing to the stainable substance being scattered through the protoplasm of the cell as a fine dust.

9. Section of the cortex of a case of general paralysis, showing acute cell changes. Magnification 250 diameters.

10. Cell of Purkinje from the cerebellum of a dog 12 days after

ligation of four arteries, showing absolutely normal appearances. Magnification 150 diameters.

11. Pyramidal cell from the cortex of a monkey, five days after ligation of two carotid arteries and one vertebral artery. Stained by the rapid Golgi method, showing gemmules on the dendrons and all the external appearances of a normal cell. Magnification 150 diameters.

12. Section of the pyramidal tract of the spinal cord of a monkey 10 days after ligation of two carotids and one vertebral. A few scattered degenerated fibres are revealed by the Marchi method. These were more numerous on the side opposite to the hemisphere on which the vertebral was ligatured, but altogether they were not more than 60 in number, so that only an inconsiderable number of the psycho-motor cells had perished as a result of the anæmia. This quite conforms with the fact that the animal had returned to the normal physiological condition when it was killed with chloroform. Dogs with four arteries ligatured and kept alive over 10 days frequently showed that a certain number of the psycho-motor neurones had perished, but the numbers were inconsiderable.

13. Swollen œdematous cell from the top of the ascending frontal convolution with diffuse staining and absence of Nissl granules from a case of status epilepticus. Magnification 700 diameters.

14. Section of the spinal cord of a case of Congo sickness with hyperpyrexia in which the temperature reached 109° F. prior to death. The whole of the cells throughout the central nervous system showed a diffuse homogeneous dull staining. The Nissl granules had entirely disappeared from the processes and the body of the cell and the stainable substance had a fine dust-like appearance. The processes are unusually distinct on account of the diffuse staining, the nucleus is clear and swollen, faintly stained, and the nucleolus is deeply stained. Magnification 400 diameters.

15. Anterior horn cell of the spinal cord from a guinea-pig which died 45 hours after injection of 0·2 milligramme of abrus globulin. Magnification 400 diameters.

16. A section of the anterior horn of the spinal cord of a rabbit 21 hours after injection of 0·01 cubic centimetre of botulismus toxin, which killed the animal. The whole of the cells throughout the central nervous system showed more or less a marked chromolytic change, as indicated in the photo-micrograph. Magnification 250 diameters.

17. Section of the diaphragm of a guinea-pig which died on the eighth day after injection of 0·0005 cubic centimetre of botulismus toxin containing 2 per cent of solids. The muscle was stained by the Marchi method and shows that quite one half of the fibres have undergone acute fatty degeneration. The dense black masses are fat cells; the degenerated muscle fibres are indicated by the diffuse black staining. The musculi papillaries of the heart showed even more marked fatty degeneration.

Figs. 1, 2, 3, 4, 5, 7, 8, 9, 13, 14, 15, 16 are photo-micrographs of preparations stained by the Nissl method. Fig. 6 was stained by the Weigert iron method. Figs. 10 and 11 were stained by the rapid Golgi method. Figs. 12 and 17 were stained by the Marchi method.

The Cavendish Lecture

ON

THE APPLICATION OF PATHOLOGY TO SURGERY.

Delivered before the West London Medico-Chirurgical Society on June 22nd, 1900,

BY HENRY T. BUTLIN, F.R.C.S. ENG., D.C.L. DURH.,

SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

[MR. BUTLIN commenced by saying that the subject of his present lecture had been in his thoughts for many years but had had to be put aside owing to the pressure of other work. He described how he had searched the records of ancient surgery in a vain endeavour to ascertain whether any of the early and firmly established operations had been initiated from a study of the pathology of the disease. First of all there was the science of pathology and what surgical inventions did come about were the result of combined observations of many men or at least of more than one. Down to the end of the eighteenth century there was but one surgical operation founded on pathology and invented and put to the test by the surgeon who had studied the pathology. This was the Hunterian operation for the cure of aneurysm. Mr. Butlin continued:—]

In spite of Hunter's example there are very few surgical inventions during the first half of the nineteenth century which can be shown to be founded on the principles of pathology. One of the best examples is the introduction of subcutaneous surgery by Stromeyer, on the foundation of experiments and observations made by Hunter half a century previously. The idea had occurred to Delpech, but he does not appear to have carried it out, and Astley Cooper had divided the palmar fascia for the relief of Dupuytren's contraction. So that here we have once more an illustration of the influence of several minds in the invention of a new method of treatment. The idea occurs to Delpech, and he suggests it; Cooper applies it in a certain limited sense; Stromeyer puts together the pathology, the suggestion, and the limited application, and introduces to the world an admirable invention. I confess to a great sense of disappointment at the fruitless result of my research. Nor was I more fortunate in finding examples of the first two relations of pathology to surgery; and I could now more easily understand how, 35 years ago, men who were disinclined to the study of pathology could make an excellent case in defence of the view that pathology is of no use in surgery.

In the early years of the second half of the nineteenth century there was little change in the relation of pathology to surgery. There was little teaching of pathology, and it would then have seemed very improbable that a new system of surgery would shortly be founded on pathology. I have elsewhere sketched the condition of the study of pathology about the year 1850,[1] especially in Great Britain, and have shown how small a hold it had yet taken on the minds of teachers or students. Yet there were even then signs of approaching change, and the most advanced and enlightened teachers were beginning to found their teaching of medicine and surgery on a more scientific basis. I have little doubt that this was part of a general movement in favour of scientific training which began about the fifties and early sixties, which questioned the propriety of the old methods of general education and desired to see them replaced either in whole or in part by science teaching, and which has since found its expression in technical and science schools, in laboratories, in science scholarships and prizes. The art of medicine could scarcely fail to feel the influence of this general movement, but the new leaven would probably have been very slowly infused into the teaching of our profession had not an event occurred which revolutionised the practice of surgery and did more in a few years to lay the foundation of surgery on pathology than had been done in as many previous centuries. In the years 1867 and 1868 there appeared in THE LANCET and *British Medical Journal* the first papers by Professor Lister on the subject of antiseptics, and his is the next great example, after Hunter's, of the discovery of a pathology and the invention of a treatment by one and the same individual. My own recollection of its early application in London is almost ludicrous. In 1868 I was house surgeon to Mr. Paget (afterwards Sir James Paget). We happened to have in the wards a man, about 40 years of age, with caries of the spine and a large abscess in the back. The results of the treatment of such cases were in those days lamentable and the man was left for some days in bed untreated. But one afternoon Mr. Paget came down and said he would try a new method of opening and treating the abscess which had been suggested by a surgeon in Edinburgh called Lister. A few days later we opened the abscess under the direction of Mr. Paget through a piece of lint soaked in some antiseptic, and then applied a little mass of antiseptic putty about half the size of my fist over the opening and a piece of sheet-lead upon the putty. That day and the following days the dressings frequently slipped down and were found half a foot or more below the wound. And in the course of a few days the cavity of the abscess became septic and the patient died, as many of those who were suffering from similar conditions did in those days.

I need not describe in detail the discovery of the causes of sepsis or the invention of the earlier antiseptic methods; the failures and successes, the opponents and partisans, and the long series of years before the principles of antiseptic surgery were generally accepted. All these things have been described again and again and are common property. I have to do with the effect of the general acceptance of Lister's discoveries on the application of pathology to surgery. The relation of micro-organisms to sepsis naturally led to the suspicion that micro-organisms might be connected with diseases other than sepsis, and this suspicion was quite justified, for it was soon amply proved by Pasteur for some of the diseases of animals. From the investigations which were undertaken in connexion with this subject the vast branch of bacteriology grew up, and as parents sometimes derive new lustre from the achievements of their offspring so did the parent-science of pathology become

[1] Address on the Jubilee of the Pathological Society of London, Oct. 20th, 1896, Transactions of the Pathological Society, vol. xlviii.

the object of greater consideration and of renewed study. At the present moment the value of pathology to surgery is no longer in question. The applications of pathology which have been made during the last 15 years have been so numerous and so important that from an absolute disbelief in the practical value of pathology we are veering round to an implicit trust in pathological foundation. As soon as the cause and nature of a disease have been discovered an appropriate treatment is looked for as a natural and immediate consequence, and if it is not forthcoming disappointment is experienced both within and outside the ranks of our profession. As such disappointments may occur with some frequency during the next few years and confidence in the use of pathology may thus be weakened—which would be very undesirable—it may be well to review for a moment the means which are now at our disposal for the application of pathology to surgery, whether those means can be improved, and how the improvement should be made.

In the first instance, there are now research laboratories in different parts of the kingdom and a good deal of money is annually expended on research. Some of this money is found by universities and colleges, some of it by scientific bodies, societies, and associations. In my former capacity of treasurer of the British Medical Association it was a great pleasure to me to see so much money devoted every year to research, but I am bound to admit that it was not always voted with alacrity. The objects of the various researches often appeared to the members of the Association to have no practical bearing, and it was suggested from time to time that the funds had better have been applied to medical defence and other material purposes. Of course, it is always difficult to appreciate the value of researches in pure science which appear at the moment to be of no more use, or likely to be of greater use, than the researches of the professors of Gulliver's University of Lagado. And I sometimes wondered myself whether the objects of research might not have been selected with a more direct view to their utility. I was, however, easily consoled by the recollection of the marvellous application of Faraday's discoveries of the relation of magnetism to electricity.[2] No discoveries could have appeared at the time and for many years after they were made less likely to have a great practical bearing. They seemed to belong to the realms of the purest science. Who would have dreamed that at this moment they would be applied to telegraphy, to lighting, to the movement of vehicles, and largely to the use of electricity in medicine? In the face of this brilliant example we have no right to assume that discoveries in pathology which appear futile or of purely speculative interest may not at some future time acquire an extraordinary practical importance.

This factor of *time* is in itself of large importance. It would not be easy to determine with precision the length of time which has elapsed between the invention of certain operations and their habitual performance. In the past this length of time must have been inordinately drawn out, even to centuries. Take once more the example of the operation for the relief of strangulated hernia. Invented in the second half of the sixteenth century, it had become a recognised operation in France in the eighteenth century, and Petit had invented and regularly practised the operation without opening the sac in suitable cases. But it appears to have been much longer in gaining a firm foothold in this country. Pott, writing some time after Petit, is well acquainted with the anatomy of hernia and with the fact that the peritoneum is not ruptured in the descent of the hernia; he is as well versed in the pathology of strangulation as Petit, and both surgeons describe it clearly and quite differently from the great surgeons 200 years before. Pott describes the operation for the relief of strangulation [3] and how the intestine and omentum should be dealt with according to their condition; but he would not resort to the operation until such means as bleeding, clysters, purgatives, and manipulation had been tried and failed. About the same time as Pott wrote Hey began to practise in Leeds,[4] where the operation for strangulated hernia had never been performed. By 1814 Hey appears to have operated on five patients and two of them had survived. To us the percentage of cures may seem very small, but in truth it was 40 per cent., and for a condition which unrelieved leads to death in almost 100 per cent. of the cases. Think what an equal success for all cases of irreducible strangulated hernia during centuries would have meant and how the principle of early resort to operation would have vastly improved the percentage of cures and have perhaps wiped out the name of *miserere mei*.

In these days the news of successful treatment travels fast—so fast, indeed, that a new method is sometimes accepted and adopted before it has been proved by the inventor. Such is the progressive spirit of the age and so abundant and so excellent are the media of communication. Of course, these are great advantages, but there is still no trace of any distinct organisation for the application of pathology to surgery. Indeed, in some respects things are likely to be worse than they were some 20 years ago. As pathology becomes more specialised the surgeon and the pathologist must necessarily be more widely separated; and although the surgeon may make great use of the pathologist in his wards they are no longer one and the same person. Problems in pathology and in the relation of pathology to surgery will arise in the minds of men who have not the time or the knowledge to work them out and who know not how or by what means to get them worked out. On the other hand, those who work at research may know nothing of the questions which occupy the minds of surgeons. On this account many problems quite worth the working may be wholly neglected or their study long deferred. If we are to remedy these defects it can only be by some more perfect organisation, such as may perhaps be supplied by my science of applied pathology. Great attention has been devoted to pure pathology and pains have been taken to educate and train discoverers. Laboratories for research are provided for them; materials and instruments are furnished; directors of distinguished ability and of approved skill in research are appointed. In consequence the work of discovery proceeds amain. The more original and the abler workers choose their own subjects of research and make their discoveries in their own way and in their own time; those who are not so original and able are assisted in their researches by the directors.

But while our schools for discoverers are good and are improving we have no school for inventors, for the men who are to make the applications of pathology in the future. It is on that account I venture to urge the importance of the science of applied pathology which may prove a fitting school for inventors as the science of pure pathology is for discoverers. I confess when it dawned upon me that my proposition would lead to a deliberate proposal to breed inventors I was at first appalled at the daring of the suggestion. Discoverers can, I know, be made, not all equally good or equally able, and great discoverers are rare and priceless. But still, discoverers can be made, and we only discuss the proper means of making them and of making them well and quickly. But what of the inventor? Is it possible to make him too? Is he not, as he was formerly thought to be, heaven-born, a direct offshoot of divine intelligence, though often poorly equipped for the struggle of life and too often destined to fall a prey to the greedy maw of the seeker after wealth? Will mere training and education suffice to produce a mind which is not of earthly origin? In order to solve this question I thought it well to make some inquiry into the lives of inventors, and as our profession can boast but few I was thrown back on the lives of general inventors, with the following result. In the first place, there can be no doubt that many men never would have invented had it not been for a chance (not always a happy chance so far as the inventor was concerned) and therefore might never have been known to the world as inventors. The overturning of a spinning-wheel suggested to James Hargreaves the idea of the spinning-jenny. The idea seems to have entered his mind like an inspiration, just as Paré said that his brain had received the inspiration of the use of ligatures to bleeding vessels. The attention of Cartwright, the country clergyman, was directed to the invention of the power-loom by an after-dinner conversation, and, without any knowledge of weaving and without ever having seen a loom at work and without any correct notion of the principle or mode of its construction, he is said to have evolved out of purely mental processes the idea of the power-loom. There must be many such men as Hargreaves and Cartwright of natural inventive genius which has never been roused into action by accident or education and who live their lives through to the end without even themselves being conscious of their talent. In medicine and surgery there are

[3] The Chirurgical Works of Percivall Pott. A new edition. London, 1779.

[4] Hey began to practise in Leeds in 1759.

also undoubtedly such men and if we are to use them we must discover and develop them.

In the second place, when once the inventor has been awakened to the knowledge of his talent for inventing he seems not only to like to employ it, but to be possessed by a resistless impulse to invent. This has been shown in the lives of many inventors. And in the curious account I have of Cartwright the book[5] says: "It would seem that the faculty of invention once aroused, its appetite for exercise is constant and insatiable. ..... An inventor he was, and an inventor he must continue till his eye was glazed and his brain numbed in death. ..... Wool-combing machines, bread and biscuit-baking machines, rope-making machines, ploughs and wheel carriages, fire preventatives, were in turn invented or improved by him."

In the third place, your inventor may invent better and with greater success if his mind has been trained in scientific pursuits. I think one of the best illustrations of this is to be found in the history of the invention of the miners' lamp. By a curious chance the safety lamp was invented during the year 1815 by two men, working apart, neither of them knowing that the other was engaged on the invention, and each working out his invention from a wholly different point of view. Both Humphry Davy and George Stephenson were highly endowed by nature. Both possessed the inventive faculty—Stephenson in a very high degree. But while Stephenson was what may be termed a natural mechanical and inventive genius, his education had, owing to his circumstances, been wholly neglected and he had only such knowledge as he had been able to gather together in a long struggle against adversity. Humphry Davy, on the other hand, was a highly educated man of science, but his inventive ability was decidedly lower than that of Stephenson. The safety lamps produced by these two men resembled each other in many respects, and a comparison of them in our Museum of Inventions at South Kensington shows how little difference there is between them. Yet one of them was invented on chemical and the other on mechanical principles. Davy,[6] at the request of certain gentlemen, undertook to try to invent a lamp for the safety of the men employed in the coal-pits. He commenced his labour by an exhaustive study of the chemical properties of fire-damp (light carburetted hydrogen), the circumstances under which it exploded, and the proportions of air mixed with it which rendered it peculiarly dangerous. By a series of admirably devised experiments, he discovered that the surfaces of small tubes prevented the explosion of the fire-damp and that this depended on the cooling power of the tubes, and he finally found that the greatest hindrance to the inflammation of the gas was afforded by a large number of small tubes or apertures, such as is represented by the numerous tiny openings through a fine wire gauze. Such a covering rendered unnecessary the use of glass or any other fusible or brittle substance, in itself no small recommendation. Stephenson tells his own story[7] of the manner in which he came to his invention. He says he knew nothing of chemistry at the time he was engaged in setting up some machinery in a coalpit. In the intervals of work he amused himself with lighting one of the "blowers" in the pit. Holding his candle to the windward of the flame he observed that it changed its colour. Two candles, drawing the flame towards them at a greater velocity, changed its colour still more and caused it to grow duller, and when a number of candles were employed the "blower" ceased to burn. Stephenson rightly attributed this effect to the velocity of the current caused by the heat of the candles to the windward of the "blower,"[8] and came to the conclusion that if he could produce a current through tubes in a lamp equal in velocity to the current he saw passing along the roof of the pit-gallery he would be able to make a lamp which might be carried into an explosive mixture without exploding externally. Repeated observation and experiment finally taught him that numerous tiny apertures afforded better protection than a small number of long and deep tubes, and his third lamp was made by surrounding the flame with a metal plate, perforated by a vast number of tiny holes, so that it differed little from a wire gauze of the same material. Stephenson was so confident of the efficiency of his lamp that he tested it, at the risk of his own life, by entering a coal-pit which had been first rendered as foul as possible by preventing the escape of the fire-damp. Davy's lamp was much more generally used than Stephenson's, but Stephenson's lamp was used for very many years in the Killingworth Pit where he had been colliery-engineer-wright at the time of its invention.

At the first sight it might seem that Stephenson's successful invention is but another proof that your inventor is born, not made; for here is a man without scientific knowledge, and without even ordinary education, who invents a lamp almost precisely similar to, and as good against explosions as, that of the philosopher and scientist, Sir Humphry Davy. But, in truth, Davy's proved to be the better lamp. Not only was it lighter and more portable than Stephenson's, but it possessed the great advantage that it was not extinguished in thick fire-damp. Further, the experiments and observations of Davy in the course of his research served to render the world richer in the accurate knowledge which it afforded of the nature and chemical properties of fire-damp. If Davy's invention had proved a failure his work as a discoverer of the nature and properties of fire-damp would have far more than repaid the time and labour expended on the attempt to invent.

Again, Davy's invention proves that it is possible to invent "to order," for he deliberately set himself to invent the lamp at the request of a committee of gentlemen interested in the coal-mines. I do not know whether we shall ever attain to that with our inventors of surgical methods. Yet a similar instance of a successful investigation and of the invention of a method of treatment, or rather of prevention, at the request of persons interested, may be found in the history of the discovery and prevention of silkworm disease by Pasteur.

Here, then, are found four important indications for the making and perfecting of inventors: that there are certainly many more inventors in the world than the world suspects, but their peculiar talent must be discovered; that when it is discovered they can scarcely help inventing; that scientific training, so far from impairing their inventive powers, will almost certainly improve them; and that men with the proper talent and opportunity may invent "to order." Further, it may be assumed that no man would be likely to make a specific invention unless he were acquainted with the need for such an invention. From these indications it would seem that if we are to make surgical inventors we must look for inventive minds among our students and young qualified men; that these men must be well versed in surgical methods at present in use; that they must be thoroughly educated in science and in the methods of science, especially in experimental methods. They must also be well instructed in pathology and acquainted with new discoveries in pathology which may be of use in surgery, and they must either have the opportunity of testing their inventions or of observing and directing the trial of them. They must therefore have free access to the hospital wards and be in frequent or constant communication with them; they must have laboratory accommodation and must be in touch with those men who are engaged in pathological research.

If these conditions are to be fulfilled in such a town as London we shall require two species of pathological laboratory for research. The one, for research in pure pathology without any reference to its application, may be of vast size and thoroughly equipped for workers, and need not be attached, so far as its site is concerned, to any hospital. The other, for research in applied pathology, the laboratory for inventors, must needs be attached to the hospital; and those who work in it should have the freest access to the wards, even if they are not in charge of special wards, and should have every opportunity of observing what is done there and in the operating-rooms. In order that they may be thoroughly instructed in the science of pathology they should be taken from among the workers in the laboratory of pure pathology and should be selected on account of their special aptitude for the work of research and for the originality which they have exhibited. They leave the school of discoverers and the science of pure pathology for the school of inventors and the science of applied pathology. At the time when the idea of a school of applied pathology first presented itself to my mind the sketch I have made would have appeared to be the dream of an enthusiast. But now so far from being a dream

[8] The rushing of the fire-damp from fissures in the strata of coal is called a "blower."

it is in some respects actually approaching realisation. There are in this town at the present moment laboratories where researches in pathology are constantly carried out, and some of these laboratories are quite separate from, and independent of, the hospitals. There is an institution of preventive medicine where pure and applied pathology are studied, but this is also separate from the hospitals. During the last few years several of the hospitals have founded professorships of pathology and have appointed to them men who devote to the science of pathology, not merely the time they can spare from some other pursuit, but their whole time. These men are constantly in touch with the work of the wards and furnish the greatest assistance to it by bacteriological and histological examinations. Speaking of my own hospital, the assistance rendered to the work of the wards by Dr. Andrewes and his predecessor Dr. Kanthack has been of inestimable value. Indeed, it is difficult to understand how we could have performed our work efficiently before the institution of the pathological laboratory.

[Mr. Butlin concluded by saying that although much had been done much remained to be done. He compared, somewhat to the disfavour of the latter, the sums of money spent in Germany on chemical research connected with the colour industry and that spent upon the same object in England. A similar kind of thing is, he said, wanted for the furtherance of medicine and surgery—in fine, a "direct and organised scheme for research and the application of pathology to our art."]

The Ingleby Lectures

ON

THE COMMONER NEUROSES OF CHILDHOOD, THEIR PATHOLOGY AND TREATMENT.

Delivered at the Mason University College, Birmingham,

BY O. J. KAUFFMANN, M.D., M.R.C.P. LOND.,

PHYSICIAN TO QUEEN'S HOSPITAL, BIRMINGHAM; LATELY PROFESSOR OF PATHOLOGY, MASON UNIVERSITY COLLEGE, BIRMINGHAM.

LECTURE I.[1]

Delivered on June 27th.

MR. DEAN AND GENTLEMEN,—I desire to draw your attention to a large class of sufferers whose ailments inflict much distress on themselves and much anxiety on their friends and parents. The diseases with which I propose to deal are the so-called functional nervous disorders or neuroses of children, as distinguished from those diseases of the nervous system in which distinct and easily recognised changes can be found post mortem to account for the symptoms during life. I have thought it more interesting to treat in these lectures of a group of maladies of common occurrence, one or other of which must almost daily come under the observation of each of us, than to deal with rare and exceptional ailments, and I have been confirmed in my choice by the conviction that much is still to be learnt regarding the nature and causation of these neuroses, and much in regard to their correct and complete diagnosis, and that something still remains to be done in the way of treating them successfully, to which end a true appreciation of their nature is the first essential step.

The disorders with which I propose to deal are the following: (1) chorea; (2) saltatory or salaam spasm; (3) tetany; (4) night terrors and dreaming; (5) nocturnal enuresis; (6) migraine and allied conditions; and (7) epilepsy. Dissimilar though these diseases may at first sight appear yet they have several points in common. Thus they occur with greatest frequency in childhood, some, as chorea and nocturnal enuresis, being almost limited to that period of life as regards their onset. Further, they are more frequent in the female sex, and where this appears not to hold true entirely, as in migraine and epilepsy, it is nevertheless the fact that females are more disposed to be the sufferers during the time of adolescence. Lastly, I think that I shall be able to show that they have still more points in common, particularly in the matter of causation.

1. *Chorea.*—This is so common a disorder that I will not waste your time with a description of its characters But I would like to draw attention to the different kinds of chorea which we encounter in practice. The following list comprises all the forms commonly connoted under the term chorea: (1) senile chorea; (2) hereditary chorea of middle adult life; (3) post-hemiplegic chorea; (4) chorea of pregnancy; (5) fright chorea; (6) hysterical and imitation chorea; (7) electrical chorea of Dubini; and (8) rheumatic chorea and those choreas arising from scarlet fever, malaria, and possibly from other infective conditions. With the exception of post-hemiplegic and senile chorea all these are genuine functional nervous disorders. It is of course true that minute changes have been discovered in the brain in cases which have ended fatally. These microscopic changes, however, are not sufficient to remove the disease from the list of neuroses, nor have they as yet been made out with sufficient constancy to warrant the inference that they are the actual direct cause of the choreic movements. It will be noticed in looking at this list that, putting out of consideration for the moment the first three, we have to deal with two broad classes of chorea. The first of these is psychical in its causation, at least as far as the exciting cause is concerned; the second class is clearly of quite different origin—namely, toxic. In the latter No. 7 and No. 8 are comprised; in the former No. 5 and No. 6; and No. 4 may belong to either the psychical or the toxæmic class.

A good deal of doubt has been expressed by different observers upon the alleged production of chorea by fright, chiefly on the ground that fright is very often asserted to have set up the disease in a child when closer investigation shows the cause of the fright to have been very slight. It must, however, be borne in mind that what may seem to a healthy adult to be a small or negligible cause for shock or fear may to the child have been a very great cause; or, to express it otherwise, what does not suffice to frighten an adult may produce very real terror in a child. There are, I imagine, few medical men of any experience who would not admit that fright is capable of producing genuine chorea, in the same way as we all know that it may, in certain conditions, set up paralysis agitans, dementia, genuine epilepsy, profound shock, and even death. However we may try to explain the manner in which fright acts, we are constrained to allow that it may result in these severe nervous disturbances, and more, that it may lead to disease which has a distinct anatomical lesion. Thus, for instance, Dr. Allbutt has described a case of chlorosis in which the anæmic condition was set up by great terror. Certainly the patient had on a previous occasion suffered from the same complaint, so that we must admit in this particular instance the presence of a strong predisposition. Now the question naturally arises whether fright or any other strong mental impression can create chorea in a child without there being any predisposition produced either by an hereditary, weak, and unresisting nervous system, or by a toxæmic condition which, though not obtrusive up to the time, has been quietly damaging the nervous centres for a period preceding the exciting cause. The evidence on this point is not sufficiently conclusive to warrant a categorical answer to the question, but I think that every now and again we meet with clear evidence that sharp mental impressions may set up chorea in children in whom nothing has before existed to make us suspect a disordered or hereditarily weak nervous system. In the majority of fright choreas, however, the evidence is very strong that an inherited or acquired predisposition is present. Apart from the agency of mental shock we have, however, the agency of toxæmia, and this cause furnishes a greater number of instances of chorea than does mental disturbance. A majority of the cases of chorea which are met with in this country show a history of some rheumatic affection, either pronounced, sharp, and severe, or insidious and lingering, and at other times so slightly pronounced as to answer to the name of "growing pains." A small number of the sufferers give strong evidence that scarlet fever was the source of the blood intoxication. In a certain proportion of the cases we can trace neither of these maladies nor any

[1] Lecture II. will be delivered on July 4th, 1900.

other infective disease, and the cause of the toxæmia remains undiscovered.

I would now like to bring to your notice a fact which has often arrested my attention in the out-patient room, when watching children suffering from chorea. This is the evidence of disordered digestion which we may observe in a considerable proportion of these patients. That sufferers from this disease are usually small, ill-clad, and ill-fed is generally admitted. Over and above this we may, however, see that they often have furred tongues and, what is very unusual in healthy children, distinct vascular stigmata on the cheeks. Inquiry will in the cases presenting these two signs nearly always elicit a story of indigestion and often of constipation. A considerable number of choreas have come under my notice presenting these appearances and giving a history of digestive disturbances. These facts naturally suggest the question whether disorder of digestion may not stand in some causal relation with chorea, and impossible as it is to prove such a causal nexus, there are nevertheless some points which, I believe, support the suggestion. Thus many of these patients showed in a marked degree the presence of indican in the urine, proving that a good deal of putrefactive material was absorbed from the bowel and passed through the liver into the general blood-stream, to be finally removed by the kidneys, but only after it had circulated through the tissues. It is true that in some cases presenting the same signs of indigestion no indicanuria can be found, but this is not surprising when we remember that profound digestive disturbances may exist without indican being discoverable in the urine. The positive evidence afforded by this body is valuable as an index of absorption; the negative evidence furnished by its absence proves nothing. I shall return later, in dealing with the general pathological aspect of these disorders, to the questions of indican and of absorption by the intestine of anomalous by-products of digestion; meanwhile there certainly is no improbability that chorea should be caused by a toxæmia due to putrefactive changes in the alimentary canal. The modern and most widely accepted explanation of the chorea which follows on acute rheumatism is that the phenomena of the disease are due to a toxic body contained in the blood and that this harmful material is a product of bacterial life. Now the putrefactive processes which occur in the intestine are likewise the work of bacteria, and there is every *à priori* reason to believe that the metabolic products of these microbes will act harmfully on the nerve centres if they be brought into intimate contact with them by the circulating blood.

Another consideration which has some interest is suggested by this—namely, the possible connexion between rheumatic fever and self-infection from the gastro-intestinal tract. It is true that we can generally trace the occurrence of a sore-throat at the commencement of an attack of rheumatic fever, but not always. When we can trace the inflammation of the tonsils or faucial regions we assume that the germs or their toxic products have gained access to the blood by way of these inflamed areas. But, as I have just remarked, this channel of infection not infrequently fails us. May it not be that in some instances rheumatic fever is set up by bacteria from the intestine effecting an entrance into the blood? The suggestion has a good deal of likelihood on its side, especially when we consider that there are several different clinical types of rheumatic fever and that in the endocarditic and articular lesions of this disease several distinct kinds of bacteria have been discovered. However this may be, I have seen so much clinically of chorea combined with evidences of digestive disorder, as to make me believe that it is, in a considerable proportion of the total cases, set up by auto-intoxication from the intestine, and therefore further investigation in this direction seems to me to be desirable; and I feel convinced that any observer who will watch cases of chorea, bearing this point in mind, will soon be struck by the frequency with which confirmatory evidence will meet him. Accordingly I would wish to insert in the list of cases of chorea another heading—namely, "gastro-intestinal self-intoxications." I am not able to give statistics from any considerable number of choreas to show what proportion of them may with probability be assigned to gastro-intestinal self-intoxication. Some years ago, however, before my attention was directed to the importance of this cause, I found that out of 24 successive cases of chorea six gave a clear and undeniable history of the first attack being set up by fright or other mental shock; one was due to scarlet fever, one to typhoid fever, and one resulted from injury—namely, a sprained ankle. (This last case may perhaps be classified with the choreas produced by shock.) Eight cases showed evidence of endocarditis or rheumatic fever, or gave a history of the latter, and in seven cases no cause whatever could be elicited by inquiry or by auscultation of the heart. I now think it highly probable, in the light of more recent experience and further inquiry, that this group of patients owed their disease to toxæmia from disordered digestion.

2. *Saltatory spasm.*—Closely allied with chorea is the curious nervous disorder which has been termed "saltatory spasm," or "jumping spasm," or "salaam spasm," from the jumping or curtseying movements which characterise it. The movements vary a little in different cases, justifying now the one name and now the other. The gap between the common clinical picture of chorea and the rare one of saltatory spasm is bridged over by certain cases of so-called "hysterical chorea," as I will endeavour to show by citing an instance in point. Saltatory spasm is so rare in England that it hardly comes under the designation of a common neurosis and it is introduced here mainly on account of its relationship with chorea. The only cases which have come under my personal notice are two, one in a woman, aged 33 years, and the other in a girl, aged 14 years, and since the disorder is so scarce I may shortly describe them.

CASE 1.—A girl, aged 14 years, who had not begun to menstruate and who presented no appearance of sexual maturity, had suffered for four days from the spasms now to be described. At irregular intervals, which, however, rarely exceeded 30 seconds, there was a sudden contraction of the flexors of the hips and of the knees. The contractions were of only momentary duration and instantly relaxed, but were often repeated so frequently as three times in five seconds. After such rapidly following movements there would be an interval of quiet, lasting perhaps half a minute, and this went on all day long and only ceased during sleep when the muscles were completely at rest. The spasms were equally marked whether she stood or lay down; but their intensity varied, so that the effect on the body was not always quite the same. Generally the effect would be a bending of the trunk on the thighs like a sudden and rapid bow; but on more forcible contraction of the muscles concerned the heels would be raised off the ground and brought down again sharply with a stamp; and on occasions the feet would both leave the ground completely for an instant and a distinct jump was the result. At much longer intervals a spasm would affect the arms, the elbows being bent and the arms being folded across the chest by the action of the larger pectoral muscles. The more highly specialised limb muscles were free and so was the face. The glutei and extensors of the hips contracted, but apparently only in re-establishing the balance of the body after the disturbing effect of the flexor spasm. There were no sensory symptoms and the patient controlled the sphincters perfectly. Her mental state was curious. She answered rationally and even cleverly, spoke clearly and without any hesitation, and sang nicely with a good voice and particularly correct intonation when asked to do so. Occasionally, however, that is, several times in the day, she would suddenly and without any apparent reason—for instance, while she was being examined in the out-patient room—burst forth into song, a thing which, her mother said, had occurred only since the onset of the present illness. At intervals, too, she would break into a fit of loud laughter without rhyme or reason, but she did not have attacks of crying. She ate and slept well and had a rosy, healthy, clean complexion, and was well built and well nourished. The history of the onset of this illness is interesting and ran as follows. The girl was in good health until three weeks before her admission to the hospital. At that time she had a sudden fright and instantly screamed loudly, but then walked home and appeared to her mother to be in her usual health. On the day following the fright it was noticed that she was nervous and quiet, but her quietness was interrupted by loud fits of laughter, the reason for which could not be ascertained, and when anyone approached her she was liable to scream loudly. In this nervous and depressed condition, with the occasional outbursts just described, she continued until four days before admission, when the spasms made their first appearance. The little girl was naturally very intelligent, industrious, and quiet, and was her mother's right hand in the housework. She

had previously to her present illness always enjoyed good health. The family history showed no special neurotic tendency. In hospital, kept quiet behind a screen, she soon recovered complete health, and though I have not seen her since I have every reason to believe that she had no recurrence for at least a considerable time. A point of great interest in this spasm is the affection of the arms associated with that of the legs. It will be noticed that the form which it took was that of folding the upper limbs across the chest very much as the motion of humility, which is associated with the bowing of the trunk on the thighs in the performance of an oriental salaam. In fact, but for the rapidity and jerkiness of the contractions they completely justified the appellation of "salaam spasm." Again, it is interesting to note the complete escape of the more highly specialised limb muscles as well as of the facial muscles; in fact, the muscular groups affected were those most elementary in development and least specialised in action. It would be easy to call the condition which I have described one of "hysterical spasm" in view of its mode of origin, and I have no doubt that by some it would be so named. But, on the other hand, we know that typical choreas are often set up in precisely the same way and I do not feel inclined to describe this case as "hysterical spasm" any more than I would describe a chorea due to fright as "hysterical chorea."

CASE 2.—The other instance of this affection, as I have mentioned, occurred in a woman, aged 36 years, unmarried, and small, badly nourished, and wizened in appearance. In her the muscles of the lower limbs alone were spasmodically affected, the arms and face escaping completely. The effect when the patient was standing was exactly the same as I have described in the case of the little girl. When the patient lay in bed, the psoas contraction tended more to arch the lumbar part of the spine into a position of momentary opisthotonos, the thighs becoming the fixed points from which the muscles acted, and the same was noticed when she assumed the sitting position. When I saw her the spasm had lasted some months, but she could give no clear history of the onset, which appeared to have been gradual. The case came to my notice long before disturbance of the digestive functions in connexion with these disorders had aroused my interest and I am therefore unable to say whether any of the former were present. The malady proved very intractable and after two months of treatment the spasm was practically undiminished.

These two cases are typical of saltatory spasm. It is plain that the mode of causation, in the first at least, was the same as in so many cases of chorea. In fact, it seems to me merely an accident that this little girl was attacked with the peculiar spasm described and not with ordinary choreic movements, and one would not be surprised, were the saltatory form commoner, to see it produced by precisely the same causes which give rise to chorea.

CASE 3.—In order to show the close clinical connexion existing between chorea and salaam spasm I will mention a case which was recently under my care at the Queen's Hospital, Birmingham. A single woman, aged 21 years, was admitted suffering from choreic movements affecting all the four limbs, the muscles of the neck, and, to a smaller extent, those of the face. The movements had the character of sudden sharp contractions followed by momentary relaxation—in fact, they resembled nothing so much as the contractions produced by the sudden application and withdrawal of a faradaic current at frequent but slightly irregular intervals. The contractions of the neck closely resembled those of spasmodic torticollis. All these movements continued during sleep. The patient was fairly developed, well nourished, and in good condition. The complexion was good with the exception of a few venous stigmata on the cheeks. Her digestion was, according to her own statement, in good order, but her bowels during her sojourn in hospital required constant attention. There was no endocarditis and no history of rheumatism or of former chorea could be obtained. The onset of her illness was as follows. Six months before her appearance at the hospital, while she was in good health, she had been bitten by a dog. She was not much hurt but greatly frightened and she ran away. For some hours after the fright she continued to tremble, and for a few days continued in a very nervous state. Three or four days after the injury her back suddenly began to arch spasmodically and intermittently, especially when she lay in bed, and for a fortnight these spasms continued to spread so as to involve the limbs; but they were at the time of admission to hospital slightly subsiding. With the patient standing up no arching of the back could be seen, but there was distinctly every now and then a flexion of the trunk on the thighs of the same kind, but of much smaller degree than in the two cases of saltatory spasm just mentioned, and the muscles producing this movement could be both seen and felt to contract. The patient also had retention of urine during her stay in the hospital. From this symptom she had suffered once before during an attack of influenza long antecedent to the present illness. She was but little benefited by a stay of seven weeks during which everything I could devise was tried, and now she is still suffering in exactly the same manner and also has attacks of retention of urine from time to time. The urinary difficulty of this patient is well worth noting; it varied between retention, which would trouble her for days together, and true suppression. Thus, after she had been an in-patient for about three weeks the quantity of urine, which up to that time had ranged within normal limits, suddenly fell to four ounces in the day, and she suffered from severe headache. Only a few drachms of urine could be evacuated by the catheter and there was no palpable enlargement of either kidney. The condition passed off with diuresis. More often than this, however, there was mere retention of urine easily relieved by the catheter. Now this case, on the face of it, is one of hysterical chorea with hysterical anuria, and the character of the movements, their rhythm, and the history of the onset all support the diagnosis of hysteria. Moreover, the family history showed a predisposition to nervous disorder. The refractory character of this illness is likewise in keeping with what is remarked by Charcot on the intractability of certain hysterical affections. Yet the spasmodic movements continued undiminished while the patient was asleep, which proves that they were independent of any active encouragement on the part of the sufferer and that the disease was as genuine a chorea as is any chorea the onset of which is determined by mental shock. I have quoted the case at length in order to show how close is the connexion between ordinary chorea and so-called hysterical chorea, and to demonstrate the clinical and etiological relationship between chorea and saltatory spasm, which latter was very closely approached in the present instance. This patient showed no indicanuria, but the venous stigmata on the cheeks, coupled with the stubborn condition of the bowels, gave good ground for suspecting a chronic auto-intoxication, and in the absence of the same it is quite possible that the original fright might have produced nothing more than a temporary shock.

3. *Tetany*.—This disease should rather be considered as a symptom, for although we do meet with patients in whom the spasm of tetany so predominates that all other signs of illness are overshadowed by it, yet such cases are rare. On the other hand, tetany is not so rare as one symptom forming part of a clinical picture in which the other symptoms and signs are of equal prominence. It is unnecessary here to describe the character of the contractures. The trunk muscles and those of the face generally escape, and it is only in very rare cases that the muscles of respiration are affected. The disease is most often met with in children, but it occurs also in women and is, among adults, limited, so far as I have seen, to the female sex. The causes commonly assigned are the following: (1) catching cold; (2) rickets; (3) acute infectious diseases, such as typhoid fever and small-pox; (4) intestinal affections, as diarrhœa; (5) prolonged suckling and over-lactation; (6) pregnancy; and (7) Weiss has pointed out a peculiarly frequent sequence of tetany after extirpation of the thyroid gland. Sometimes tetany has been reported as occurring epidemically, but it is doubtful whether in these cases the spasm was not due to imitation.

CASE 4.—With a view to show the connexion of tetany with another class of disease only indirectly referred to in the above list of causes I would quote the case of a nurse who came under my observation some time ago. She was a strong and healthy woman, but had caught cold and become hoarse a few days before I first saw her for violent suffocative spasm with much cyanosis. After the spasm she looked quite well and her healthy colour returned, but she was completely aphonic. A subsequent laryngeal spasm which I saw was accompanied by typical tetany-contractions of the hands and of the right foot, the left remaining free. The limbs affected were blue and cold, but recovered their natural colour and temperature when the dyspnœa ceased.

The suffocation was apparently caused by an adductor spasm in the larynx exactly similar to that which is so familiar in children as laryngismus stridulus. For five or six days these attacks recurred both by day and night. During the whole of this time she had a moderate continued fever which ended gradually by lysis. The spasm in the hands, which occasionally came on in slight degree without the dyspnœic attacks, was invariably preceded by a sensation of numbness and tingling which gave her warning of its approach. After leaving her sick room this patient was weak, pale, and tottery, as though she had undergone a long and severe illness. Throughout, the lungs had presented no physical signs of disease. Here, then, was a typical case of tetany associated with laryngitis from cold and adductor spasm of the larynx, a symptom-complex which brings this instance of the disease very near indeed to those tetanies which occur in rickety children in whom both laryngismus stridulus and catarrhal laryngitis with stridulous spasm are exceedingly common.

CASE 5.—Another case of this malady which was recently under my care is also worth noticing. An infant, aged one year, was admitted for well-marked, though not very severe, tetany. He was well nourished but showed distinct marks of rickets. In three days, the spasms having subsided, he was sent home. Ten days later he was re-admitted for a recurrence of tetany. The stools were now loose and contained some orange-peel and other undigested food; they were greenish, mixed with mucus, and very offensive. The tetany now persisted for 11 days, being nearly always present in some degree, but generally appearing to cause no pain; the exacerbations, however, were painful. On the eighth day he developed a laryngeal cough but had no laryngismus. Throughout there was an absence of fever and gradually the child regained his normal health. In this case we have a combination of the symptom of tetany with several of its recognised causes—namely, gastro-intestinal disturbances, clearly provoked by unsuitable and indigestible food, as shown by the stools, rickets, and most likely considerable laryngeal inflammation. I have never seen tetany occurring even in a rickety child without distinct catarrh of either the respiratory or the digestive mucosa, and it seems to me that not the rickety nutritional trouble but these catarrhs are the cause of the spasm, by inducing a toxæmia or a reflex irritation. We have seen that such inflammations can lead to tetany in the absence of rickets, and the truth is probably that both the latter disease and the tetany are common results of the catarrhal conditions. It appears more usual for such results to follow disease of the intestinal than of the respiratory mucous membrane.

Tetany is one of the diseases in which Albu has succeeded in isolating from the urine a toxic substance. In the light of other researches this result is not so important as might at first sight appear; I shall return to this subject when reviewing the general pathology of these neuroses. Meanwhile we find in the occurrence of tetany in conjunction with extirpation of the thyroid and with laryngeal inflammation a suggestion that reflex irritation may have a share in leading to the spasmodic symptom. So also it might be thought that in the case of the little patient last quoted the spasms were set up reflexly by irritation of the intestinal nerves, and apart from any absorption of toxic material from the lumen of the intestine. It must be admitted that it is very difficult to distinguish between nervous symptoms set up by a toxæmia and those caused by the peripheral irritation of correlated nerve fibres. There appears to me to be only one point which may help one at the bedside to determine whether the nervous symptoms in any particular case are toxæmic or reflex. It is this: when we produce a reflex act by mildly stimulating the skin, as, for instance, in eliciting the plantar or cremasteric or epigastric reflexes, the first response is always in muscles which lie near to the stimulated cutaneous area. Thus in the case of the plantar reflex, in health, flexion of the toes is the first muscular action, and only as the stimulus is increasing do other muscles respond. On the other hand, when a toxæmic state is the cause of the muscular symptoms the poisonous material will be equally distributed in the blood-stream, and it will act with greatest effect on that part of the nervous system which is most susceptible to the toxic influence, or, what is probably the same thing, that part, for the structural elements of which the poison has the strongest affinity. Hence the seat of the muscular contraction will in this case be determined by the tenderest part of the central nervous system and we may, as I shall have occasion to show later, have such a phenomenon as unilateral epileptic convulsions arising from gastro-intestinal self-intoxication. From the phenomenon of tetany, as well as from the evidence that the disease is always preceded by conditions liable to produce toxic or infective states of the blood, we should be inclined to say that the spasms are produced by toxic rather than by reflex mechanism. A co-existence of the two agencies is not, however, entirely excluded.

4. *Night-terror.*—The next disorder which I wish to discuss is night-terror—nightmare and troubling dreams generally. Children are comparatively rarely brought for advice for these symptoms alone, but their frequency is very great in conjunction with other conditions—notably with disturbances of digestion. Probably the dreams are a good deal more troublesome to the little sufferer than the child can express, for it is only when the fifth or sixth year has been reached that a child will complain of its dreams. In younger infants the evidence of suffering must be derived from screaming, or, in lesser degrees, from restlessness, muttering, and broken sleep. One may say that dreams and nightmare arise from the following causes: (1) primary mental or emotional excitement which prevents the occurrence of that necessary anæmia of the brain in which alone sound sleep is possible; (2) pain, palpitation, visceral uneasiness, &c., producing a consciousness of the physical sensation and thus preventing sound sleep; and (3) blood-states which irritate the nervous centres. In the first class of cases the patient, generally an adolescent or adult, will recognise what is troubling him. It rarely happens that the sensation is one of mere restlessness without a definable cause for the same. The second group of causes requires no comment; it is, of course, equally liable to operate in children and in adults. The third group of causes prevents sleep by producing a sense of restlessness without pain, and an excited state of the consciousness, in which deep sleep is impossible, and in which confused thought goes on, and any impression made on the half-slumbering senses will render the sufferer partly conscious of the same. Most of us engaged in the practice of medicine are familiar with the phenomenon which may be called "red dreaming." In this condition the sufferer sees the object of his dream coloured a vivid red and bloodshed forms a common subject of these sleep-hallucinations. It is not infrequently a salient complaint in the tangled complex of symptoms which a so-called "hysterical" woman lays before us. All the instances of this kind with which I have become acquainted have occurred in people whose digestive processes were out of order. It is safe to say that a large number of dreams, more particularly those of an acutely distressing or alarming character, and especially the dreams of children, are due to a toxæmic state; and it is to be noted that, apart from the delirium of fever, these dreams occur frequently in children who are to all appearances fairly healthy or who are, at all events, not suffering from pronounced disease and who can usually follow the daily round of school-life. If we inquire what kind of digestive disturbances are the most fertile in producing dreams we shall often find that a faulty diet is to blame. Referring, again, for an example to the red dreams just mentioned my own experience shows them to be frequently due to a single excess of meat accompanied perhaps by a simultaneous overloading of the stomach. It may be, therefore, that such dreaming is caused by reflex irritation of the brain-centres or of the nervous apparatus which governs the supply of blood to these centres. On the other hand, it is also possible that the importation of an excessive amount of the digestive products of a meat meal acts as an irritant to the brain-cells directly and without the mediation of the vaso-motor mechanism. However we may choose to explain the connexion we must admit it from clinical observation, for it is proved not only by the frequency of the joint occurrence but also by the effect of treatment which removes the gastro-intestinal cause. It is true that success does not always follow immediately upon correction of the dietary error, and two reasons are accountable for this failure. The first is that, though unsuitable feeding is often the primary cause and is easily put right, yet the faulty diet may have produced a state of intestinal catarrh and this may in itself be sufficient to perpetuate the nervous symptoms, and will therefore require appropriate treatment. The second reason is that frequent recurrence of the nervous effect may establish a morbid habit in the nerve-cells which is in itself a difficulty even after the primary cause of the disturbance has been successfully removed.

Although, as I have insisted, improper feeding is the most frequent primary cause of children's disturbed sleep and dreaming, yet the same symptom is met with in patients in whom the diet is everything that could be wished. In such cases we shall usually find the presence of gastro-intestinal catarrh, shown by a coated tongue or painful digestion, and it is often the remnant of an attack of measles, whooping-cough, or other infectious disease the acme of which is passed. In other cases the dreaming is the only marked symptom of an unrecognised febrile process, either tailing off from some previous disease, or arising insidiously without marked symptoms, or, though much more rarely, representing the gradual onset of a general disease such as acute rheumatism of the creeping insidious type. It is therefore advisable to take the temperature, at all events in the evening, in patients in whom dietary or digestive faults fail to account for the disturbed sleep. In adults dreaming is frequently set up by a toxæmic condition which arises, not from self-intoxication from the intestine, but from the inefficiency of the kidneys, the result either of actual disease or of the state of renal inadequacy described by Sir Andrew Clark; and in children the same condition will at times be found both in cases where albuminuria and the presence of renal débris reveal structural disease of the kidneys, and in others where these glands are merely enfeebled by the demands to which a previous infective condition has subjected them.

The number of instances in which I have found distressing dreams combined with the signs of digestive toxæmia, to which reference has been made under chorea, is considerable. Yet in laying stress on what I believe to be the most frequent and important cause of nightmare—viz., gastro-intestinal disorder—I would not underrate the importance of primary emotional excitement and of pain, and of unrevealed fever in producing the same effect. In order to treat a child successfully for this distressing condition it will be found necessary to discover fully the cause of the disturbance and to deal with this in the first instance. Further details on the treatment will be included in the review of the therapeutic measures which are applicable to these neuroses generally.

5. *Nocturnal enuresis.*—This condition is, I suppose, still regarded by some as an independent disease and is treated as such. I wish to show in these remarks that that is not really the view which should be taken of this common and annoying symptom. Mothers and fathers are accustomed to regard enuresis as a bad habit—and such undoubtedly it may become—but it is never a habit contracted from either mere wilfulness, or from imitation, or for the sake of producing a pleasurable sensation, and the only habit which can be considered as applying to enuresis is one of easy excitability of the cord-centres which control the muscles of the bladder. Punishment is clearly out of place in the treatment of a habit of this kind. For the first factor of nocturnal enuresis we must, however, look elsewhere, and I think that the primary causes may be fairly stated as follows: (1) disease of the bladder or urinary passages, as, for instance, stone; (2) irritation of the rectum, as from worms; (3) excessive secretion of urine; (4) excessive irritability of the spinal centres concerned in micturition; or (5) excessively irritating quality of the urine. Although it is convenient to separate the fourth and fifth causes, and although, in fact, each of them may be singly operative in causing nocturnal enuresis, yet these two factors will, as a rule, be found acting conjointly. Excessive irritability of the spinal centres there always must be, to lead to the untimely discharge of urine during sleep, but this probably never occurs (except in gross disease of the spinal cord with which we are not here concerned) without a condition of urine which must be considered as abnormal. If we exclude those cases in which there is an excessive formation of urine and those in which there is actual organic disease of the urinary passages, we shall find that the urine of children suffering from enuresis is generally sharply acid, often, in addition, rich in urates, more rarely depositing uric acid; sometimes an excess of oxalate of lime will be found. Such urines are scanty and concentrated rather than copious, and they indicate an error of the metabolic processes which may depend upon disease or diathesis, or upon faulty diet. In conformity with these points we generally observe that enuresis first comes on either after an illness or after a change of diet, or when, in the absence of definite illness, the child has been in depressed health. The state of the urine is, in fact, the index of a disordered metabolism. How the disorder comes about is shown to us by the forerunners of the enuresis, though it must be admitted that the history is often difficult to obtain. We may safely assert that the disturbance of the assimilative and disassimilative processes is never primary, but that it is invariably the result of an altered state of the blood, which in turn has its cause in the presence of toxic substances, the proceeds of microbial action or the derivatives of a faulty diet. In a few instances nocturnal enuresis results from the direct excretion of pathogenic bacteria by way of the urine. Charged with considerable quantities of living bacteria and their derivatives, the urine naturally has an action upon the walls of the bladder irritating beyond the normal, and the result is that during the time when voluntary control is smallest the spinal centres are apt to respond vigorously to the extraordinary irritation. I have lately seen a case in which this occurred.

CASE 6.—After a prolonged pneumonia the urine of a little boy contained large quantities of bacteria, and simultaneously he had great frequency of micturition with loss of control over the bladder. This led to an enuresis which was certainly not limited to the night, but which continued night and day; but it was merely an exaggeration of nocturnal enuresis.

The same tendency to frequent micturition may be discerned in a minor degree in a good many adults after the termination of pneumonia or other bacterial disease such as enteric fever. There can, however, be no doubt that the majority of instances of nocturnal enuresis are associated with no very noticeable disturbance of the general health and hence the enuresis is made the chief complaint, and, I repeat, where no recent illness can be traced there we shall nearly always find error of diet or disease of the digestive tract. Unsuitable diet plays so important a rôle that to illustrate it I will mention a case which has recently come before me.

CASE 7.—A little girl, aged three years, suffered from nocturnal enuresis together with frequent micturition during the day. The urine was said to be not excessive in quantity, it had a high colour and density and a strong smell, somewhat resembling that of meat extract. There was a little inflammation about the external genitals. The child's sleep was broken, she was nervous, and she had a trick of pulling faces, the movements coming sometimes near to those of chorea. Beyond this her appearance was that of health. She suffered, however, from itching and showed isolated spots of urticarial erythema. All these symptoms had come on from the time when she was first given meat; up to nearly her third year she had never tasted this article of food and had enjoyed excellent health. Withdrawal of meat from her dietary was immediately followed by moderation, though not by complete cessation, of the symptoms; but a fortnight after the beginning of this treatment a single meat-meal, which by the way consisted of rabbit, was followed by enuresis in the same night.

DIFFERENTIATION IN DIABETES.

BY F. W. PAVY, M.D. LOND., LL.D. GLASG., F.R.S.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

(*Continued from p. 1789.*)

IN the "*alimentary*" form of diabetes we have only the ill effects of the sugar in the system to deal with. There is not the liability to the supervention of the fatal coma that there is in the other form where toxic products are developed from the process of tissue breaking-down going on. In proportion to the amount of sugar in the system, which is indicated by the quantity appearing in the urine, so do we find the intensity of the symptoms. With only a little sugar reaching the system and passing into the urine there is but little deviation from the natural state, and nothing wrong as regards the state of health may be perceptible. When the circumstances are such, however, that more sugar finds its way into the circulation the deviatio from the natural state becomes, proportionately to the quantity, increased and there is a corresponding manifestation of disordered health. That it is the passage of sugar

through the system that is the source of the troubles met with in connexion with the disease is shown by the immediate amelioration that takes place on causing the passage of sugar to cease simply by recourse to an appropriate diet. Let a case be taken in which from some circumstance or other the complaint has been allowed to run on uncontrolled till an urgent state has been produced. The patient is now placed upon a diet preventing, by the exclusion of carbohydrate matter, sugar reaching the system as before. A change of a most marked kind immediately sets in. All the symptoms subside and the health becomes restored and may afterwards be indefinitely maintained so long as the condition does not advance beyond the "*alimentary*" form. Thus in these cases as long as there is only the "*alimentary*" type of condition to deal with the state of the patient depends upon the management adopted. With a diet properly adjusted to meet the precise extent of impaired assimilative power existing there is virtually nothing in operation to produce abnormality. It is true, looked at in its entirety, that we have not a perfectly normal state before us. The power of properly disposing of carbohydrate matter is lacking, but if the demand is not made for the exercise of the absent power nothing abnormal is observable. It is only when the demand is made and not responded to that evil consequences arise; and it is to the presence of sugar *per se* in the system that the result is due.

To set things really right the restoration of the defective assimilative power is wanted. This, whilst often in a certain class of case to a considerable extent attainable, is not so much at our command as could be desired. The prevention, however, of the baneful effects of the sugar arising from unassimilated carbohydrate matter stands upon a different footing and in the "*alimentary*" case can be reckoned upon as attainable. But everything depends upon the concurrent compliance of the patient with the required attention to the necessary management. If this is not loyally rendered serious consequences are sure to follow. Sooner or later the toxic influence of sugar in pronounced quantity reaching the system will assert itself and produce characteristic troubles of various kinds attended with a general decline of power, all of which might have been averted—I am speaking of a case controllable by diet—by keeping the sugar under. The contrast in the progress of patients where the sugar is kept under and where it is not is very marked. In the one there is nothing to interfere with the maintenance of health whilst in the other health and strength fail till by some concurrent ailment the patient is carried off.

Any number of cases might be brought forward in illustration of what I have stated. I will content myself with citing the following case, in which one of the most common of the baneful effects of sugar in the system—viz., peripheral neuritis—was encountered in a very severe form. The patient first consulted me in the autumn of 1895. He was then 51 years of age and had been the subject of diabetes for a year and a half. He was on a partially restricted diet and his urine contained 55·54 per 1000 of sugar. In four days, under the altered treatment adopted, including the restricted diet, the sugar had fallen to 16·66 per 1000 in the urine passed at night and 12·50 in that passed in the morning. Three weeks later the sugar had disappeared. A month after this three ounces of ordinary wheaten bread per diem were allowed without bringing back the sugar. About six weeks later he was taking six ounces per diem and passing no sugar. Six months elapsed, the patient had dropped his treatment and the urine had returned to the state it was in when I originally saw him. The date now reached was July, 1897. Restriction of diet immediately altered the condition and throughout 1898 a fairly satisfactory state was maintained. On Nov. 15th, 1899, the patient was brought to me in a deplorable plight. His urine contained 68·40 per 1000 of sugar, and he was suffering from urgent thirst and the other ordinary accompaniments of diabetes. His legs were affected with peripheral neuritis. The pain in them prevented his obtaining sleep at night, and there was such hyperæsthesia that he could not allow one to rest upon the other or find an easy position for them in bed. There was the usual loss of knee-jerk and from the ataxic state existing he could not walk alone. The condition soon yielded to treatment, the sugar becoming at once reduced to only a small amount without being completely lost. On Feb. 1st he was free from trouble in his legs and the sugar then stood at 9·30 per 1000 in the night specimen and traces in that of the morning. On Feb. 21st the report was a trace of sugar in both night and morning specimens of urine.

It is the passage of a case from the "*alimentary*" into the "*composite*" form which gives a serious aspect to the outlook. The liability to the occurrence of this transit varies with the associated circumstances. Age, as is well known, constitutes an important factor in connexion with the matter. Our prognosis has to be founded upon the knowledge supplied by experience of the progress observed in association with the particular collateral circumstances existing. We may have to deal with the disease, at the time being in the alimentary form, in an elderly and in a young subject. Experience tells us that the issues to be looked for are respectively very different.

In the young subject marked progressiveness constitutes the great feature noticeable, and it is this which gives the formidable character to the complaint that it possesses at this period of life. Treatment which at an early stage of the case proved readily efficacious in subduing the symptoms in the course of time loses its effect, and advance having been made to sugar being drawn from the tissues the urine can no longer be brought into a sugar-free state. The rate of progress varies in individual cases: the younger and more sensitive the subject the more likely is the advance to be rapid. The worst subjects for the complaint are those of a highly-strung nerve organisation, those who are disposed to worry over or meet with friction the ordinary events of life, and those who without such a nature are placed in a position to involve exposure to mental disquietude. A deviation from the ordinary progress sometimes presents itself in cases with a hereditary history. As a rule, these cases show no difference from those without such a history, but I can say from experience that now and then instances present themselves where even setting in at childhood the complaint may run on for several years without making any serious progress. It seems as if a flaw in the chemistry of life had been handed down which takes a long time in attaining full development. Amongst members of the Jewish race the complaint is not only particularly common but heredity is very conspicuous. As a counterbalance I consider it may be said that the progressive tendency is not so pronounced as amongst other people. Above middle age a marked diminution of the progressive tendency is noticeable, and thus an opportunity is afforded for a success in treatment not attainable in young subjects. In many cases if taken early—and this I am under the impression is a point of considerable significance—the assimilative power may become so far restored as to permit of an ordinary diet being taken without being attended with the passage of sugar.

A patient whom I saw for the first time in September, 1896, stands as a striking example of this result. He was then 57 years of age, and about three months previously had been sharply attacked with thirst, polyuria, and wasting. Diabetes was recognised, and under an altered diet the urgency of his symptoms became subdued. When I saw him he was on a partially restricted diet, and his urine contained 35·71 per 1000 of sugar. Codeina was ordered in conjunction with the fully restricted diabetic diet. In two days the sugar had fallen to 10·2 per 1000 and three days later it had disappeared. He increased in weight and in every way improved till towards the middle of November, when somewhat suddenly a fall in weight set in with a feeling of prostration like that which he had experienced at the beginning. He was under the apprehension that a relapse had occurred. His urine was in a sugar-free state, and I have mentioned that under such circumstances the symptoms presented indicate returning assimilative power and want of carbohydrate. Three ounces of ordinary bread per diem were allowed and improvement immediately followed. At the end of November the amount of bread was raised to 4½ ounces. On Dec. 23rd the weight was again falling and weakness was complained of. The condition was satisfactorily met by increasing the bread to 6 ounces. In the early part of February, 1897, the bread was raised to 7½ ounces. At the end of July a satisfactory state existed. In the entry for Sept. 24th, just after my return from the vacation, it is stated that through passing more urine and losing weight the patient feared there might be a return of sugar and that he had on his own account reduced the bread with the effect of producing a marked loss of weight. The allowance was raised to 9 ounces and recovery of weight took place. In October the bread was increased to 10½ ounces, and in December to 12 ounces. A steady rise in weight had now set in and was afterwards continued. I see it noted that

between Oct. 21st and Nov. 11th there was a gain of 3 lb., between Nov. 11th and Dec. 9th 8 lb., from this to Jan. 6th, 1898, 5 lb., then to Feb. 3rd 3¼ lb., March 10th 3½ lb., May 3rd 7 lb., and June 14th another 7 lb. The patient was now taking starchy food in the form of potatoes in addition to his bread, and in December, when he had put on 8 lb. more weight, it was considered advisable to draw in somewhat as he was becoming too corpulent. He is a thorough disciplinarian with a strong desire to do everything to maintain his health. I last saw him in December, 1899, when he was in a good firm condition and passing urine free from sugar.

From time to time cases of this kind present themselves but more frequently the restoration of assimilative power advances to a more limited extent and then remains stationary. Variation in the point attained exists, and in the position thus to be dealt with starchy food within the limit of assimilative power regained does not throw sugar into the urine, whilst beyond the limit it does. Such a state of things may go on without any appreciable alteration for months and years, the urine all the while constituting a tell-tale of when the food taken has exceeded the tolerating power.

Extending our survey, cases are come across in which in the course of time the tendency for the assimilative power to grow weaker shows itself, but in these cases the rate of progress is not to be compared with that typically belonging to the disease in young subjects. It is observed that food which at one time failed to give rise to the passage of sugar at a later period does so, and that after the lapse, it may be of many years, the complaint passes from the "*alimentary*" into the "*composite*" form. The following is a case in point.

A patient whom I first saw in 1885, and who was then 48 years of age, had no difficulty by moderate attention to diet in keeping his urine free from sugar. In the early "nineties" considerably stricter attention, which was not steadily given, was needed for the purpose. So the case has run on, the urine being sometimes for a while kept free from sugar and at other times not. According to the latest evidence recorded the sugar has ceased to be removable from the urine by diet. In April last the urine upon a strict diabetic diet contained upwards of 30 per 1000 of sugar and gave an indication of the presence of both diacetic and oxybutyric acids. The case, therefore, has now passed from the "*alimentary*" into the "*composite*" type of the disease.

In concluding what I have to say upon this part of my subject I consider that I cannot lay too much stress upon the importance as a measure of treatment of exerting our endeavours in the first place to put, and afterwards steadily to maintain, the urine in a sugar-free state, but whilst accomplishing this object no further curtailment of carbohydrate food should be made than is found to be necessary for the purpose. My experience decidedly leads me to say that without a removal of the sugar, whereby the aid of a natural state of system is supplied, no restoration of assimilative power is likely to occur. Freedom from mental strain and friction is a great adjuvant in treatment.

THE "COMPOSITE" FORM OF DIABETES.

In this form of diabetes we have a twofold source for the sugar—the carbohydrate of the food and a morbid breaking down of tissue. Through this latter process being attended with the formation of supplementary products which pass with the sugar into the urine means are afforded for recognising the condition. We are placed, also, in a position to check the account given by a patient. If there is no indication of the presence of oxybutyric acid revealed by the results supplied on estimating the sugar by cupric oxide reduction and by the polarimeter, or of that of diacetic acid by the ferric chloride test, it may be concluded that the sugar existing in the urine has been derived from ingested carbohydrate of some kind or other. If it be asserted that none has been taken, error, wherever it may lie, must exist in the statement. If it should happen that deception is attempted to be practised it is the patient who will have to bear the self-inflicted harm, but it must not be lost sight of that carbohydrate may easily in an accidental way be unconsciously taken, and sometimes the source of delusion is the diabetic food consumed in the place of ordinary bread which wrongfully fails to represent what is professed.

Oxybutyric acid requires careful manipulation and an experienced worker for its reliable employment as a source of information, but much advantage is gained from the knowledge which it supplies. In the first place its presence means a more or less advanced stage of the tissue breaking-down process, and thereby a nearer approximation to the liability to the supervention of diabetic coma, than does that of diacetic acid; and in the next its amount can be definitely read off, through which again information is supplied bearing on the prospect in relation to coma. As has been mentioned it is through its left-handed rotatory power that its determination is effected. When present with dextrose the neutralising effect which it produces on the dextro-rotatory reading that would be given by this body reduces the figures obtained and thus throws them below those given by cupric oxide reduction. Further, when the dextrose is fermented away with yeast the urine is left with the levo-rotatory activity belonging to the oxybutyric acid present.

I have in an earlier part of this communication spoken of the Gerhardt, or ferric chloride, test, which is the test employed for diacetic acid. The amount of the principle present is judged of by the intensity of the colour produced and it is convenient in recording it to represent it by one, two, or three + signs. From the record before me of about 250 observations I can personally testify to the value of the information that is afforded by the method of examination to which allusion has been made. Naunyn and some other authorities have published results which agree with mine. We must not look too rigorously for uniformity in all cases in the results obtained. Discrepancies here and there occur, as yet without apparent reason, in the difference between cupric oxide reduction and optical activity compared with the optical activity after fermentation. It has been suggested (Külz and others) that a certain amount of levulose is sometimes present with the dextrose, and other conjectures have been put forward. Upon this point of detail there is room for further inquiry, but taking the series of results as they stand linked together in a given case they speak in a manner that cannot be mistaken. For the purpose of illustration I will take some representative examples from my collection and give them in a tabulated form.

19·2	13·6	7·2	+ + +

It is, as I have already stated, the passage of the case from the "*alimentary*" into the "*composite*" type that supplies the bad foreboding. Many cases run on for years without the transition occurring and if the sugar is properly kept down no harm arises. A patient consulted me in February, 1886. He was then 51 years of age and had been the subject of diabetes for one and a half years. His symptoms were severe and his urine contained 50 per 1000 of sugar. In a specimen of urine recently examined sugar was present but oxybutyric and diacetic acids were absent. Length of time, however, in the "*alimentary*" form affords no guarantee against the passage of the case into the "*composite*," but my experience would lead me to say that the more completely the elimination of sugar is kept under the less likely is the transit to occur. The case cited above of the patient whom I first saw in 1885 serves as an illustration applicable here. After running on for about 15 years in the "*alimentary*" form progress has recently been made into the "*composite*" form. In December last there was a slight amount of diacetic acid present without any oxybutyric acid. In April considerable quantities of both existed.

As an example of rapid development of the "*composite*" form (and I do not know that it may not in some cases set in with the onset of the disease) I may refer to the case of a female patient, aged 18 years, of a very sensitive organisation whose first symptoms of diabetes occurred in November and who was brought to me in February with urine containing much sugar associated with large quantities of oxybutyric and diacetic acids.

When the abnormal tissue breaking down, which is attended with the production of sugar and the associated products that have been referred to, sets in it is obvious that a serious aggravation of the previous condition becomes established. Under the morbid influence in operation the tissues melt down into unexhausted products which escape as waste with the urine. No wonder under these circumstances that the weight should cease to be maintained. A sensibly advancing fall is noticeable and when the patient survives for some time without being carried off by coma or otherwise, marasmus may progress till reduction almost to the semblance of a skeleton is attained.

The diabetic coma to which the patient in the "*composite*" form of diabetes so frequently succumbs is the result of a true autotoxicosis. The term "acetonæmia" has been applied to the condition from the idea formerly entertained that acetone was the toxic agent. If there is a pronouncement, however, that can with confidence be made it is that the term, as in the parallel instance of "uræmia," is an entire misnomer. From the evidence in our possession neither acetone, diacetic acid, nor β-oxybutyric acid can be looked to as possessing the toxicity needed to account for the coma. A proposition has recently been put forward which has the appearance of being entitled to our weighty consideration. Sternberg [1] has suggested that it is to β-amido-butyric acid, a probable precursor of oxybutyric acid in the acetone series of products, that diabetic coma is attributable. The view is supported by the fact that after the experimental introduction of the β-amido-butyric acid into the circulation exactly the same train of symptoms, even to the "air-hunger" kind of breathing, follows that is met with in diabetic coma. Grube [2] has repeated these experiments and obtained completely confirmatory results.

That a within developed toxic agent is the source of the coma is strikingly exemplified by the effect of a measure of treatment that has been upon occasions resorted to. By the intravenous injection of large quantities of various saline solutions patients have been restored from a comatose to a conscious state. Unfortunately the effect has only been temporary. The toxic agent, it may be assumed, has for the time been washed out of the system, but owing to the genetic action going on has soon reaccumulated.

The reaction with the ferric chloride is not necessarily to be taken as indicative of a bad foreboding. There are circumstances under which diacetic acid is only temporarily present and it is only when persistently in some quantity present that it is to be concluded that a grave condition has been reached. With starvation and an excessive amount of proteid food, apart from diabetes, ferric chloride may be found to give a reaction and the reaction may appear for a time when a diabetic patient is first put upon the restricted diet to disappear subsequently when the system has adapted itself to the altered food. I have seen this sometimes occur. In the experimental pancreatic diabetes the sugar is accompanied by diacetic acid and its associates, and such is also the case in phloridzin glycosuria when fasting is conjoined. Under these several circumstances a supply of carbohydrate matter contributes to the removal or reduction of the principles. Fat also appears [3] to act in a similar way. It seems as if the carbohydrate and fat groupings within the proteid molecule saved the nucleus of the molecule, and that when these are absent the molecule itself undergoes destruction. Placed in such an extremity, with the dangers of Scylla and Charybdis before us, we may consider it wise to steer a middle course in relation to food.

THE PRIMARY DISORDERS OF GROWTH.

BY HASTINGS GILFORD, F.R.C.S. ENG.

(*Continued from p. 1648.*)

THE method which has been adopted to show the class unity of the various diseases which have been mentioned may be termed the synthetical method, for it consists in the construction of the class from its elements. The propositions which are embodied may be "proved" by the converse or analytical method—i.e., by taking individual diseases and showing how each one answers to certain tests which are common to the class. Many of the diseases under consideration are so unlike one another that it at first seems almost impossible that they can have similar bases. This may be said, for example, of such divergent diseases as local giantism of the extremities, primary Bright's disease of the kidneys, pernicious anæmia, and Addison's disease. But there are other diseases of the group which connect these together and make it easier to grasp their essential identity. Thus, while it requires some effort of the imagination to see the connexion between, say, a giant extremity and a large white kidney, it is but a step between the giant hand and the giant breast. Further, the process which gives rise to the giant breast is evidently of the same nature as that which produces the giant thyroid of goitre. The latter, it is true, contains, as a rule, large numbers of cysts; but that is a detail which results, not from any difference in the nature of the disease, but from peculiarities in the structure of the gland itself. From the fibrous or cystic thyroid to the fibrous, large white, or cystic kidney is but another step, and so the connexion between the giant hand and the giant kidney is completed. After the same fashion it can be shown that there are all stages between the purely fibrous adrenal body and that which is composed almost solely of tubercle-like cells or is unquestionably tuberculous. Moreover, that the process which leads to destruction of the adrenal body in Addison's disease is essentially of the same nature as that which gives rise to cirrhosis of the liver or to primary Bright's disease of the kidney is also indicated by the occurrence of cases in which adjacent parts of the liver and kidney are implicated by contact with diseased adrenals. Under this circumstance a local change is set up in these organs which is exactly the same as that which takes place in cirrhosis and in Bright's disease respectively.[1] But the primary nature of the lesion of Addison's disease and its identity with the fibrous degenerations of the lungs, spinal cord, liver, and kidneys have been already dealt with by Sir Samuel Wilks.[2]

In the course of the study of these primary disorders of growth it soon becomes evident that there are certain rules or postulates which bind them together and which greatly help in their elucidation. Some of these are so important and so absolute that they almost deserve the more dignified name of laws. Of these, two of the most important are that "any organ or part which is capable of growth is

[1] Professor Burdon Sanderson, Transactions of the Pathological Society of London, vol. xx., p. 38.
[2] THE LANCET, June 13th, 1885, p. 1101.

subject to the primary disorders of growth" and "the greater the fluctuations of natural growth the greater is the liability to disorders of growth." A good example of the operation of the latter rule is to be found in the female breast, which is both subject to many changes of growth in health and is also, perhaps, of all organs the one which is most liable to the primary growth diseases, from a simple hypertrophy to the ultimate descent into cancer. A good instance of the application of the first of the two rules is to be found in the growth diseases of the blood. It is, I suppose, certain that the blood must be regarded as a fluid tissue, one of whose functions is to act as a medium; and being a tissue and capable of growth we know that, like all other tissues, it must also be liable to the disorders of growth. Only two of these need now be referred to. One is hypoplasia, or pernicious anæmia, the other is degenerative hyperplasia or leukæmia. In pernicious anæmia the cells of higher type (red discs) are alone diseased, the less differentiated white cells not being affected. The explanation of the course of events in pernicious anæmia may be put briefly as follows. In health there is provision both for the destruction of imperfect or used-up red discs and also for the making of new discs to take their place. Red bone marrow is the chief source of the new blood, while the blood itself, and after it the liver, kidneys, and spleen, are the organs which are most concerned in the scavenging process of blood destruction. In pernicious anæmia there is a perversion of the natural processes of blood growth which leads to the appearance of a number of badly formed or embryonic discs, instead of well-made, healthy discs. But the blood destroyers cannot distinguish between these defective discs and those which are used up in the normal wear and tear of the body; they therefore ruthlessly break up and destroy in the blood all the imperfect cells as rapidly as they can. But increased destruction of red discs leads to their increased formation and a spurious hypertrophy of the red marrow takes place in consequence. In this way the vicious circle of bad workmanship, increased waste, and increased output is completed. A similar process goes on in connexion with the white cells in leukæmia, though it is varied in accordance with the variation in the nature of the tissue which is affected. The leukæmias are obviously the degenerative hyperplasias of the blood. Their clinical history is in the main that of other forms of primary degenerative disease. They are sporadic, idiopathic, progressive but liable to periods of amendment, pernicious, and incurable. They are distinguished by increase of cells of low type (leucocytes) and decrease of cells of higher type (red discs). Running with this is spurious hypertrophy of one or other of those organs (the lymph glands, the spleen, &c.) which are concerned in the making of leucocytes, corresponding with the pseudo-hypertrophy of the red marrow in pernicious anæmia. This morbid process may be of mild degree, lasting for years, or it may run a fiercer course, cutting short the life of the individual within a few weeks, and being in all important respects indistinguishable from a sarcomatosis. But whether it lasts for a long or a short period it is equally a vice of growth, essential in nature, dependent upon no tangible cause, but due to a radical retroversion of tissue to a condition of savage independence.

Having glanced at some of the less evident forms of primary growth disorders it will now be best to choose some one organ and pursue its disorders through their various forms. Perhaps one of the best that can be chosen for such a purpose is the skeleton.

THE PRIMARY GROWTH DISORDERS OF THE SKELETON.

A. *Hypoplasia of the skeleton.*[3]—This is a disease which has not hitherto been systematically described, though it sometimes shows itself in very marked forms. Its features are as conspicuous and as clearly defined as are those of rickets or cretinism. Two of the best known instances are those of Charles Stratton (Tom Thumb) and his wife (see Fig. 1). There is a skeleton of another in the museum of the Royal College of Surgeons of Edinburgh, and of another in the museum of the Royal College of Surgeons of England. The principal features of the disease are as follows. It is prone to occur in more than one member of the same family. It is a form of dwarfism, and its peculiarities will perhaps be best understood by comparing it with other kinds of dwarfism and especially with rickets. It is distinguished from all other forms by marked delay in the rate both of growth and development of the bones while the intelligence is not affected. Most other kinds of dwarfism are due to defects of growth only, and in all of them bone growth is more affected than bone development. The subjects of hypoplasia probably never attain their normal stature, though growth continues until long after it has usually ceased. It is probable that the soft tissues of those affected with this disease follow a rule, which may be termed that of adaptation of growth, to distinguish it from that which is known as correlation of growth, which has not quite the same meaning. A good example is afforded by rickety dwarfs, in whose case the growth of the muscles and other soft parts does not continue to any extent after the bones have ceased to grow, but becomes adapted to the requirements of the stunted and deformed skeleton. Adaptation of growth is still better shown in this hypoplasia of the bones, where it is even more perfect than it is in rickets, for the rickety dwarf has muscles which are often in excess of his needs, and is, therefore, too strong for his size and of a thick-set and clumsy appearance. Hypoplasia, moreover, differs from rickets in that while in rickets the adaptation is one of growth only, in hypoplasia of bone it affects development as well. Rickety dwarfs pass through the various stages of life like men and women of common stature, whereas in these other dwarfs the appearance of youth, manhood, and maturity are greatly delayed or do not appear at all. The growth and development of the bones are delayed, not arrested, and the growth and development of the soft parts follow suit. Immaturity of the bones is associated with immaturity of the rest of the body. This is shown especially in the face and in the general proportions of the figure. Adult dwarfs of this type may have the faces and proportions of young children. They have, as a rule, broad faces, snub noses, large broad heads, and short limbs. Puberty may not come on until after the age of 30 years, or it may not appear at all. At the same time this immaturity is one of appearance only, for these dwarfs, as a rule, die as soon as, or sooner than, ordinary individuals. There are, however, some notable exceptions.

Associations.—It is probable that, like other primary growth disorders, hypoplasia of the skeleton is prone to be associated with defects or excesses of other parts. Very few cases of this disease are recorded, but among them is one in which such an association is mentioned. Mr. Hutchinson[4] has described a case of dwarfism in which there was marked immaturity of appearance and which to all appearance was an example of this same disease. This man was affected with another growth anomaly in the shape of hyperplasia of the gums. One case is reported in which the hypoplasia seems to have taken on degenerative characters. This case is described by Dr. Paltauf in his monograph on Dwarfism (p. 41). Together with marked delay of ossification there was osteomalacia which was the cause of death. There was also cirrhosis of the liver.

B. *Hypertrophy of the skeleton.*—While hypoplasia occurs as a form of dwarfism hypertrophy is only found among those who are tall or gigantic. It is not yet possible to say where giantism of this type ends and acromegaly begins, or what is the exact relation between the two. Some writers hold that giantism is always due to acromegaly, but this opinion has not as yet been substantiated. On the contrary, there seems good evidence for the view that there are cases of giantism which are quite unconnected with acromegaly. There are instances on record of giants who have differed from the acromegalic in having lived to the average duration of life, in the enjoyment of good health and in the possession of offspring. A good example of this form of giantism is furnished by the celebrated Mongolian giant Chang. Though it is not stated that he had children Frank Buckland[5] and others who saw him say that he showed no signs of disease and was of good intelligence, strong, and healthy. He himself stated that his brothers were giants. He is said to have died at the age of 47 years. Captain Bates, who was 7 feet 2½ inches (2·19 metres) in height, and Mrs. Bates, who was 7 feet 5½ inches (2·27 metres), were also good examples of the same condition. The Austrian Winkelmeyer who was described by Virchow[6] was another. (See Fig. 2.)

In hypertrophy of the skeleton adaptation of growth is, as a rule, obviously defective, the growth of bone being often

[3] It is impossible to do justice to this subject within the limits of this article. All that is intended is to show that there is such a condition as primary hypoplasia of the skeleton.

[4] Edinburgh Medical Journal, New Series, vol. i., No. 2, p. 117.

[5] Curiosities of Natural History, 4th S., p. 10.

[6] Zeitschrift für Ethnologie. 1885, S. 469.

conspicuously in advance of that of the soft parts. Those affected with this disease are therefore inclined to be disproportionately tall, thin, weak, and shambling in gait. Doubtless the chief, if not the only, reason why adaptation is so imperfect in giants is because in their case the disease shows itself at a later age and so much more rapidly than is the case with hypoplasia. The latter commences in childhood and continues through the rest of life, whereas giantism begins, as a rule, at or near puberty and is completed at the ordinary period of cessation of bone growth. The one runs its course slowly and so gives time for the growth of the soft parts to be accommodated to the growth of the bones; the other is so rapid in its course that the growth of the soft tissues is soon left hopelessly in the rear. Hypertrophy of the skeleton, like hypertrophy of other organs, is often by no means well defined, but merges imperceptibly in different cases into normal growth. The bones of giants are often decidedly coarse in texture, but there seems to be no evidence that the process ever goes so far as to become degenerative and to lapse into osteitis deformans.

Heredity; associated disorders.—Perhaps the best instance of the hereditary transmission of giantism on record is that of Captain Bates and Mrs. Bates,[7] whose first child weighed no less than 22¾ lb. (10·77 kilogrammes) at birth. Instances of giantism occurring as a family disease are also recorded. Giantism is so rare that the association with it of other growth disorders has much significance. One of the earliest cases is mentioned in the Bible. It is there said that Goliath of Gath had a brother who was a giant and that he had a son of "great stature" who had on every hand six fingers and on every foot six toes.[8] An instance of the family association of giantism with superfluous digits is also recorded by Mr. R. C. Lucas[9] who, in giving a genealogical tree of a family liable to the latter disorder, put at the head a great-great-grandmother who possessed no deformity but whose son was said to have been exhibited as a giant and who had a daughter with six toes on each foot. The second child of the latter had six toes on each foot and grew to be a man of over six feet in height. Several other children and grandchildren had webbed supernumerary digits and two were

afflicted with hare lips. We also read of a German giantess[10] who lived in the reign of Queen Anne and had neither hands nor feet. In the same book is an account of a male patient who possessed marked feminine characters, and another instance of this association is related by Dr. Hallopean.[11]

C. Degenerative hypoplasia of the skeleton.—Perhaps the most conspicuous feature of this complaint is unusual fragility of the bones. It is, in fact, one of those diseases which are grouped together under the loose name of fragilitas ossium. Many instances of undue brittleness of the bones are caused by the presence of new growths or are the result of long disuse or have some other known origin. But among them we also find some which are dependent upon no ascertainable cause but seem to arise spontaneously in bones which are affected with a special dyscrasia. It is these that are now referred to as instances of degenerative hypoplasia or metaplasia of bone. Some of them approach osteitis deformans in their symptoms and appearance, while others more closely resemble osteomalacia. It is probable that the degeneration sometimes starts in the substance of the shafts and gives rise to the one disease, and sometimes in the marrow and gives rise to the other. A good instance of the osteomalacic form of degenerative bone hypoplasia is furnished by Mr. Clinton T. Dent.[12] In this case the disease first showed itself by fracture of a bone at the age of four months. Bending of bones then took place, and at the age of 29 years, when the account was written, the case differed in no essential particular from one of osteomalacia. Numerous fractures had occurred, there was extreme softening of the bones, with characteristic deformity, and the only distinction from osteomalacia that was of any consequence consisted in the shafts being smaller instead of bigger than usual. The skiagram which illustrates the paper shows that while the epiphyseal ends of the long bones were very large, the diaphyses were even smaller than they are in health, thus reversing the relative proportions of these parts as they occur in ordinary cases of osteomalacia. But after all this is only to be expected in a condition of hypoplasia. In this

FIG. 2.

Hypertrophy of the skeleton (Winkelmeyer). Giantism probably not associated with acromegaly. The growth of the soft parts is not well adapted to the increased growth of the bones. X marks 25 inches. The central figure is 7 feet 6 inches (2·28 m.) high, so that the figures of "General and Mrs. Tom Thumb" would reach about to the giant's knee had they been drawn to the same scale.—(From a photograph by the London Stereoscopic and Photographic Company, Limited.)

connexion the following case is most instructive, for it not only serves to indicate that there is a relation between the idiopathic form of osteopsathyrosis, and osteomalacia and osteitis deformans, but it also helps to show the position of osteopsathyrosis as a growth disorder.

FIG. 3.

Degenerative hypoplasia (or metaplasia) of the skeleton. The chief features of this case are curvature, fragility, bending, tumour formation, and congenital dislocations of the radii.

The patient (see Fig. 3) was an unmarried woman, aged 38 years, who was 4 feet 7 inches (1·67 metres) in height, whose father was tall (6 feet 2 inches), and whose mother was of ordinary height. Neither she nor her parents had ever had syphilis or rickets. Her troubles began when she was just able to run alone, at which time she broke her right humerus. From this time onwards the story of her life is the story of a succession of fractures and tumours. At the age of six years she broke the left humerus and shortly afterwards both bones of the right forearm; when she was 16 years old both bones of the right leg were broken; and at the age of 33 years the left tibia. When she was 36 years old she broke two ribs while coughing, one of them snapping while I was in the act of binding up the other. At about the fifteenth year of her age the right leg became curved without apparent cause, and when she was 16 years old a tumour appeared on the left femur and grew so quickly that within three months it extended from the top of the bone to the bottom, and gradually hardened. While lying in bed because of this swelling the left leg became bent as the right had been. At the age of 34 years a small, hard tumour of the size of a hazel nut appeared above the right external malleolus, and in her thirty-seventh year another—of the same nature, but of larger size (as big as an orange)—sprang from the right humerus. Finally, a much smaller and more diffuse swelling appeared on the projecting part of the left tibia.

The general health of this patient is excellent and there are no evidences of either rickets or syphilis. There is a congenital forward dislocation of each elbow limiting pronation of the forearm, and, to a less degree, supination as well. There appears to be no cup to the head of the radius and the shaft of that bone is longer than usual. The shaft of the ulna is bent near its upper extremity. The tumours are apparently composed of bone and cartilage.

Mr. J. Hutchinson[13] has drawn my attention to a case under his care which bears a remarkable likeness to the one which I have just described. This patient, who was a girl aged 10½ years, showed the following lesions—viz.: (1) fractures of the right forearm (three times), the left forearm (twice), the right leg (three times), and the right thigh (all these fractures united without leaving any very evident traces); (2) absence of the external condyle of each humerus so that the finger could be placed on the upper end of each radius; (3) bending of each ulna in its upper third and of each humerus; and (4) formation of tumours of the lower half of the right femur and also of the middle of the left femur. The former subsequently disappeared but the latter had not gone when the account was written.

The various lesions which characterise these two cases may be summed up under four headings: (1) congenital malformations; (2) unusual fragility of bone; (3) bending of bones owing to abnormal softness; and (4) tumour formation. Now I think there can be no doubt that these two cases are examples of the same disease. It also seems certain that this common disease of which they are representatives is closely related to osteomalacia and osteitis deformans. All three are characterised by fragility of bones, by softening and bending, and by a tendency to be associated with the formation of tumours. They therefore show a resemblance in three out of the four main features of the above two cases.

It would be by no means difficult to bring forward a series of cases to show that there is an unbroken connexion between the various forms of primary (idiopathic) bone disease. Idiopathic osteopsathyrosis might in this way be shown to merge on the one hand into osteitis deformans and on the other into osteomalacia. The widespread, but slighter, cell insubordination of osteitis deformans might next be seen giving rise to those local cell riots which we call tumours, fibrous, cartilaginous, or bony. Finally, as the expression of the loss of every vestige of restraint, would come the periosteal sarcomata. Or, beginning again at osteopsathyrosis and tracing it on to osteomalacia, we should next arrive at the innocent myelomata and end at the malignant endosteal sarcomata. Some good instances of these two series of changes may be found in von Recklinghausen's contribution to Virchow's Festschrift.[14] In one of his cases (that of a patient, aged 66 years) there were: (1) bending of the bones, (2) irregular thickening, and (3) formation of tumours, cystic, bony, and fibrous, among them being a spindle-shaped swelling of the upper part of the diaphysis of each femur. Though the anamnesis was very defective von Recklinghausen considered the disease to be osteitis deformans of very long standing, commencing, indeed, in all probability within the first ten years of life. Hence the first onset of the osteitis deformans came within the age which is favoured by osteopsathyrosis. He alludes to a case recorded by Virchow of "diffuse deforming osteitis with tumours and cysts," and he himself gives other cases of a similar nature. Some of these were allied rather to osteomalacia than to osteitis deformans. Thus in one, which occurred in a woman, aged 55 years, there was pronounced bone softening together with cystic growths. Von Recklinghausen himself considered it to be a case of modified osteomalacia. In another were cysts, numerous fractures, and a very thick calvarium. In yet another there was "fibrous osteitis," together with multiple sarcomata, and many fractures. His opinion was that in this last case the bone softening was primary and the sarcomata secondary. He then mentions a case recorded by Hirschberg of a similar nature, which also was considered by that observer to be primarily one of osteomalacia, the disease favouring the formation of cysts and sarcomata, and giving rise to fractures. Mr. John Langton[15] has also recorded an instance of the association of idiopathic fragility of bones with the formation of tumours. In this case the first fracture occurred at the age of 11 years and was followed 17 years afterwards by the breaking down of the union of this first fracture and the growth in the bone of a spindle-celled sarcoma. It seems clear from these and other cases that there is no dividing line between osteopsathyrosis, osteomalacia, and osteitis deformans. They run one into the other, have a similar clinical basis, and,

[13] Archives of Surgery, vol. ix.
[14] Fibrous and Deforming Osteitis, Osteomalacia, and Osteoplastic Carcinoma in their Comparative Relations, 1891.
[15] Transactions of the Clinical Society of London, vol. xxix., p. 36.

making allowances for differences of tissue or age, show similar anatomical changes.

We now have to ask ourselves—(1) What is the cause of the association of these diseases with tumours? and (2) why are the two cases of osteopsathyrosis first mentioned associated with congenital malformations? The answer to the first question is almost implied in what has already been said. There is every reason to suppose that all three diseases are degenerative affections of bone or marrow and that, like other degenerative diseases of growth, they constitute favourable soil for the growth of tumours. In this respect they resemble the degenerative hyperplasias of the epithelial layers of the tongue, and similar degenerative overgrowths of the thyroid gland, the stomach, the prostate, and other organs. The answer to the second question arises out of the answer to the first. Their association with congenital deformities is best explained on the ground that these deformities are themselves primary growth disorders of a similar nature, though occurring at an earlier age. Primary excesses and defects of growth are in all probability of similar nature at whatever age they occur, and however differently they may manifest themselves, whether they occur as clefts or atrophies in fœtal life, as defects or excesses at any age, or as those localised outbursts which we call tumours.

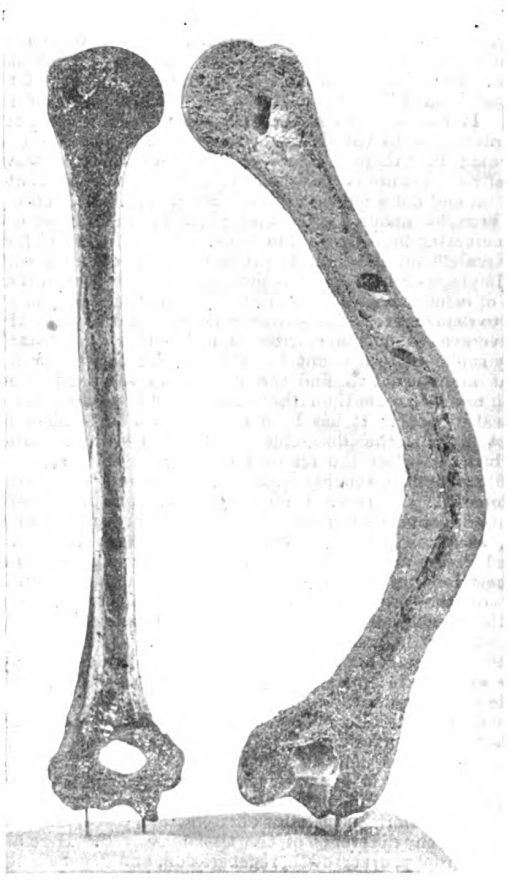
Anatomy.—In the account of the histological features of this disease which are given by Professor Hamilton[16] it is evident that up to a certain point the minute anatomy is the same as that of osteitis deformans and of osteomalacia. The structural resemblances of these two latter diseases will be dealt with later. Professor Hamilton, who quotes Langendorff and Mommsen, and gives two good plates, says that there is "dilatation of the Haversian canals which are in part transformed into medullary spaces. The cement lines (von Ebner) which intervene and map out the borders of the Haversian systems have almost vanished. The borders of the trabeculæ of bone stain red with carmine, probably owing to their being deprived of their calcic salts." The bone marrow is red and hyperæmic, full of cells and poor in fat. It resembles fœtal marrow (Virchow). Giant cells are present in the dilated Haversian canals. Cyst-like cavities are also found. Parts of the trabeculæ may be purely fibrous. All this might be said of either osteitis deformans or osteomalacia. The only real differences between them are that osteopsathyrosis is the more chronic and tends to affect both marrow and bone indiscriminately. Whereas in the other two diseases the process is more active; the changes are more pronounced and tend to affect one tissue (marrow or bone) much more than the other.

D. Degenerative hyperplasia of the skeleton.—This is of two kinds, according to whether it begins in the bone marrow (osteomalacia) or in the shafts of the bones (osteitis deformans). The differences between them are not radical or essential but are due to differences of tissue, age, sex, and function alone. The evidence of their essential identity runs through their whole clinical history and morbid anatomy. Their relation one to the other and their true pathology may be demonstrated, therefore, by passing in review their main clinical and structural features.

1. Osteomalacia and osteitis deformans have the same clinical basis. Both are sporadic, though osteomalacia, like other primary growth disorders, is much more prevalent in some districts than in others. Both make their appearance without any evident cause and both destroy the functions of the part they affect. Both run a course which is progressive but at the same time not altogether even, for it is broken up, as a rule, by intervals of quiescence or of actual betterment. These intervals are sometimes so conspicuous as to lead to the hope that the disease has ceased and whatever drug is in use when the amendment takes place usually receives the credit. But almost invariably a time comes, sooner or later, when the disease makes further headway, and though improvement may again take place, yet the end is nearly always the same. The prognosis is unfavourable. Both diseases are, in short, sporadic, idiopathic, pernicious, progressive though irregular in course, and medicinally incurable. The diseases resemble each other also in certain minor details. Thus both may begin in one bone and may be confined to that bone; both are, as a rule, imperfectly symmetrical; both are attended with similar aching pains, both affect the shafts of the bones more than the ends, and in both the disease has no direct influence on other organs. They are local disorders. Both are distinguished by bending of the bones, both by fragility, though this is more pronounced in osteomalacia than in osteitis deformans.

2. The two diseases are anatomically similar. The appearances which may be seen in the marrow of a bone affected with osteomalacia may be summed up in four words. They consist of atrophy, overgrowth, regeneration, and degeneration. The atrophy affects cells of higher type, especially the bone corpuscles, which may be seen to be decidedly shrunken in that part of the shaft which borders on the marrow. The overgrowth is chiefly of the marrow, which undergoes immense increase in volume, but is also, to some extent, of the lymphoid tissue which runs up the Haversian canals. Degeneration is well seen on the outskirts of the diseased area where the marrow touches the shaft of the bone. It first shows itself as decalcification. This is, as a rule, attributed to the action of some acid, such as lactic or carbonic; but there appears to be no evidence whatever that any such cause is at work. It is far more likely that it is a vital and not a mechanical or chemical process, and that it is brought about in the first place by the pressure of the increasing marrow on the bone. It resembles, in fact, the decalcification which is produced by aneurysms when they impinge on bones, but is perhaps more obvious in these cases of osteomalacia because of the inherent tendency of the bone to degenerate. There seems no reason to doubt that the overgrowth of the marrow is under this circumstance amply sufficient to account for this decalcification, for it is not at all unusual to find the marrow in a malacic bone taking up more room than the marrow and bone together of the healthy bone. It has been noticed that in some cases, if not in all, the decalcified layer is not immediately absorbed, but after the removal of the bone salts splits up into fibres, and so, roughly speaking, reverses the order of its development. It recedes step by step from a calcified, organised, connective tissue into a decalcified, unorganised mass, as primitive as the embryonic tissue from which it started. But along with this widespread overgrowth and degeneration there is an equally widespread attempt at repair. Most of the swelling of the marrow is, in fact, due to growth of embryonic material, consisting principally of round cells with little or no intervening fibres. But the fresh growth is itself stricken with the same blight as the tissue which it is apparently intended to repair. It is quite unable to mature so as to serve any useful purpose, and in course of time it also succumbs to degeneration. Granular and fatty changes take place in the cells until they disappear in a structureless débris. Or fatty degeneration may continue until there is ultimately nothing left in the marrow cavity but oil, which pours out when the bone is cut into.

In osteitis deformans similar changes take place, modified, however, by the difference of the tissue involved. Here also we have atrophy, overgrowth, regeneration, and degeneration. There are atrophy of the more highly developed cells of the bone, overgrowth of the more lowly calcified connective tissue of the lamellæ, and the interstitial growth of fresh deposits of badly formed material. There is overgrowth also of the lymphoid tissue of the Haversian canals, with degeneration into cells which resemble those met with in inflammation. This widening of the canals and their occupation by embryonic tissue correspond with the similar changes which take place in osteomalacia. While osteomalacia is distinguished by false hypertrophy of the marrow, in osteitis deformans there is false hypertrophy of the periosteum, leading to the deposit of new bone; but the new material which is so laid down is, as in similar hyperplasia of other organs, not only redundant, but of bad workmanship. It is imperfect bone, resembling that which is found in the fœtus, and corresponds again with the embryonic tissue of the marrow of osteomalacia.



3. There is reason to believe that the two diseases may occur together. Some of the cases of osteitis deformans and osteomalacia which are reported in the medical journals present features which are characteristic of both diseases. This has already been alluded to when we were dealing with the subject of degenerative hypoplasia of the skeleton. One of these cases is described as an instance of arrested osteitis deformans and another as osteitis deformans affecting a single bone. One has been described by Mr. J. R. Lunn,[17] who says of it that "from the microscopical appearance it appears to be a case of osteomalacia occurring in a single bone of an

[16] Text book of Pathology, vol. ii., part ii., p. 837.

[17] Transactions of the Pathological Society of London, vol. xxxviii., p. 266.

old man" (the patient was 86 years of age). "On first examining the case it seemed to be one of senile atrophy with curvature." Now this specimen is preserved in the Hunterian Museum (No. 1241, E.), and I have to thank the Council of the Royal College of Surgeons of England for permission to reproduce a photograph of it (see Fig. 4). It is

FIG. 4.

put on the same shelf with specimens of osteitis deformans. In the description of it, which appears in the catalogue over the names of Mr. Lunn and Mr. Shattock, it is said: "This specimen appears to be allied to cases of osteitis deformans affecting only one bone." It will be noticed that there is very little thickening except at the curve, but the bone has the coarse gritty look of the bone of osteitis deformans, while, on the other hand, there is an aggressive growth of the marrow causing absorption of the cancellous tissue at the upper end. The appearance of this specimen as a whole is certainly not that which is characteristic of osteitis deformans, and neither does it much resemble that which is ordinarily seen in osteomalacia, but it is equally true that in just those respects in which it differs from one disease it approaches the other in character. A better example of mixed osteitis deformans and osteomalacia it would be difficult to imagine. The specimen is such a good one that I was very rightly not permitted to obtain a piece for further microscopical examination. But I think there can be very little doubt that it is an example of a mixture of osteitis deformans and osteomalacia.

When the membrane bones of the skull are affected in osteomalacia they may closely resemble the appearance which is produced by osteitis deformans. This is well shown in a specimen of osteomalacia of Dr. J. F. Goodhart's which is preserved in Guy's Hospital Museum. The calvarium in this case is coarse, granular, devoid of diploë, and deeply scored by the trenches which have been made by the blood-vessels. The sutures are obliterated and were the bone only a little thicker and more compact it could not be distinguished from the skullcap of osteitis deformans.

These are instances of the conjunction of the two diseases. There are other specimens in the London museums which appear to show a similar mixture.

4. Both diseases are allied to inflammation. Both may apparently start as the result of injury, such as a kick on the shin. In osteitis deformans especially the anatomical changes are remarkably like those met with in inflammation, and where the disease is confined to one bone it may be very difficult, or even impossible, to distinguish it from a diffuse osteitis and periostitis due to syphilis, or, possibly, to injury. But as a rule the wide and regular distribution of the disease in osteitis deformans, the progress from bone to bone and from one part of the body to another, the absence of definite cause, the absence of fever, the selection of a special age for its occurrence, the tendency to heredity, the progressive but interrupted course, and the uselessness of the iodides and of surgical treatment suffice to distinguish between them. Lastly, and of most importance, there is one fact which by itself is sufficient to distinguish between the two, and that is the absence of motive. Inflammation must in all cases have some cause, for in this is the essence of an inflammation. Inflammation is the manifestation of the resistance of the organism to injury. Yet no one has found any fungus or other foreign body to account for osteitis deformans, and from what we know of the disease it is most unlikely that such will ever be discovered.

What has been said of osteitis deformans may also be said in effect of osteomalacia. It, too, is like an inflammation, but is in some respects very different and falls short also in the one essential of motive. It may be started by inflammation and may become the seat of inflammation, but is yet not in itself inflammation.

5. Both are allied to, and may become the seat of, tumours. Perhaps no diseases are so difficult to distinguish from one another as osteomalacia and some tumours of bone marrow. Indeed, in some instances of widely disseminated cancer of the marrow it may be impossible to say during life whether the primary disease is an endosteal sarcoma or whether it is due to osteomalacia. Their origin, history, symptoms, and course may be almost identical. Sarcomatous marrow may also closely resemble the marrow of osteomalacia in structure. In fact, healthy red marrow is so like sarcoma tissue that a widespread degeneration of red marrow into round-celled sarcomata does not leave much room for such an intermediate stage as that of osteomalacia. There can be no wonder that the two are occasionally mistaken for one another. The same happens sometimes with the corresponding diseases of other lymphoid structures, such as the lymphatic glands. It may be impossible to say in a given case whether the disease is Hodgkin's disease or a sarcomatous growth. A localised idiopathic swelling of lymphatic glands under a sterno-mastoid muscle may with confidence be regarded as a sarcoma (potato sarcoma of Mr. Hutchinson), while an idiopathic swelling of numbers of lymphatic glands in various parts of the body is as certainly due to lymphadenoma; but intermediate cases occur which cannot be positively called either the one or the other. In the same way, while ordinary cases of osteomalacia are unmistakeable, some of the reported cases of widespread sarcomatosis of bone marrow are remarkably like those of osteomalacia. Indeed, it is not easy to see how a generalised sarcomatosis of marrow, and of marrow only, can take place unless there is some alteration in this tissue, such as would be caused by osteomalacia, to predispose to it.

There is every reason to believe that the hyperplasia of osteomalacia may form a breeding-ground for new growths secondarily, as the expression of a further loss of cell-control, in the same way that the goitrous thyroid gland, the fibrous and degenerated breast, the tongue of ichthyosis linguæ, and, in rare cases, the liver of hepatic cirrhosis, may severally become the seat of malignant disease. It seems certain that this is what also takes place in osteitis deformans, for the bones in that disease are peculiarly liable to become the seat of cancerous tumours. This is in part to be explained on the ground that the tissues in general become more liable to this extreme form of degeneration as they increase in age. But in addition to this there is also an undoubted special proclivity of the hyperplastic bone

itself. It has already advanced to a half-way stage and the final descent into cancer becomes, therefore, so much the more easy.

The myelomata and sarcomata occur more frequently than the carcinomata, because these growths are more nearly related to skeletal tissue. The myelomata seem to have the same relation to these hyperplasias of bone and marrow that the fibromata have to ordinary fibrous hyperplasias, such as those of the hands in macrodactyly and of the thyroid gland in goitre. They appear to be manifestations of degeneration in a more localised and concentrated form. Connecting links between the myelomata and osteomalacia are not infrequent. Myelomata and osteomalacia may also occur together. Of this mixture a good instance is described by Hirschberg,[18] in the case of a man, aged 38 years, who had had osteomalacia for at least four years. After his death numerous cysts were found scattered through the substance of the long bones and small myelomata were also present in the substance of one tibia. Another case is described by Mr. Butlin[19] of a man who was affected with three small myeloid tumours, two being in the jaw and one in a rib, and who ultimately died from exhaustion produced by osteomalacia. An examination of some of the specimens of osteomalacia in our museums would, if one may judge from their naked-eye appearances, almost certainly show that this conjunction is by no means infrequent. The occasional occurrence of multiple myelomata is also suggestive of the presence of some generalised bone dyscrasia which predisposes to tumour formation. Nothing would be so likely to form such a breeding-ground for tumours as hyperplasia of a degenerative character, however slight it might be in extent. Myelomata also occur with osteitis deformans. Thus, Mr. B. Pitts and Mr. S. G. Shattock[20] give details of a case under Mr. A. O. Mackellar's care in which a growth having all the characters of myeloid disease occurred in a tibia affected with osteitis deformans. Other cases might be quoted. It is not improbable that some of the heterologous tumours which are occasionally found in cases of osteitis deformans are not in reality secondary to the disease, but occur only in association with it as the expression of a common morbid tendency. An instructive case which appears to support this view is reported by Mr. C. E. Richmond.[21] Spontaneous fracture of a femur had occurred in a patient who was affected with scirrhus of the breast and numerous growths which appeared to be secondary to it. On post-mortem examination cancers were found in the iliac crests and elsewhere. A section of one femur showed that that bone was not the seat of cancer but that it had undergone degenerative changes characteristic of osteitis deformans. Here it seems probable that the malignant disease and the osteitis deformans were not immediately connected, but were the associated outcome of some dyscrasia which was common to both.

6. The two diseases are prone to be associated with congenital and other disorders of growth. Dr. Goodhart has described a case of osteitis deformans occurring in association with lymphadenoma.[22] The patient was a man aged 65 years at the time of death. He was greatly emaciated. There were "many fleshy tubera apparently of a cancerous nature in the loin, and several firm, fleshy, cancer-like glands in the mediastinum and abdomen. One or two small nodules of growth in the pleura." The spleen was full of large circumscribed yellow masses and presented the typical appearance of a hardbake spleen of Hodgkin's disease. Dr. Goodhart was of opinion that these nodules and masses of growth were of a lymphomatous nature and that they were certainly not sarcomatous. He considered the case to be an example of the "interesting association of Hodgkin's disease of the spleen with osteitis deformans." There is also an instance reported of the occurrence of osteomalacia and lymphadenoma in the same person. This case was described in 1861 by Professor Perrin,[23] who calls it a general hypertrophy of the "whole of the ganglionic lymphatic system" with softening of the tissue of the bones. The age of the patient was 68 years. His disease began with swelling of the axillary glands seven years before. The bones became unduly brittle (there were five fractures) and were so soft that they could be cut with a knife. As nothing is said of the presence of heterologous tumours and the glandular enlargement was widespread there is every reason to believe that the bone softening was due to true osteomalacia and that the glandular swelling was also primary.

In glancing over the reports of cases of osteitis deformans again and again it is seen to be allied with some other degenerative growth disorder, either in the same individual or in some other member of the same family. Bright's disease, imbecility, optic neuritis or atrophy, choroiditis, retinal hæmorrhages, goitre, emphysema, carcinoma, sarcoma, molluscous outgrowths, and subcutaneous fatty and cartilaginous tumours are all mentioned in different cases. Special attention is called by some writers to certain of these associations, such as that with malignant tumours, with bulbar paralysis, or with degeneration of the posterior columns of the spinal cord. These degenerative disorders seem to occur far more often in association with osteitis deformans than they do among those of the same age who are not affected with this disease. The same may be said of osteomalacia. A good instance of its association with different degenerative disorders is published by Dr. George Dock[24] who, in describing the osteomalacia of a woman, aged 24 years, says that her father had had syphilis; the mother possessed a goitre as large as a man's head and had suffered from "rheumatic" pains of the limbs while she was carrying her first child (suggesting possible osteomalacia). A brother had a congenital deformity of the right thumb, while the patient herself had a goitre, a cartilaginous tumour of the right femur, and was found after death to be affected with fibrous degeneration of the spleen, the kidneys, and the ovaries. In the reports of other cases we find cleft palate, goitre, exophthalmic goitre, cataract, chronic Bright's disease, hydromyelus, and syringomyelus. Such diseases are not infrequent, but the most common of all are degenerative affections of the central nervous system. These are so common as to lead to the belief that osteomalacia may be directly produced by some trophic disturbance originating in the brain. It is possible that the general defect of nutrition which characterises some forms of insanity may predispose to osteomalacia or other growth disorders, but there does not seem to be any other relation between them beyond that of the association of allied diseases. They seem to be related rather as brothers and sisters than as parents and offspring.

7. Both diseases show evidences of hereditary transmission. Although the early forms of bone metaplasia (osteopsathyrosis) are often hereditary, among the few cases which I have been able to find the influence of heredity is apparently more often shown in osteitis deformans than in osteomalacia. In neither can the evidence of heredity be termed convincing, though it is more than suggestive. There appears to be no example of the detailed description of two cases from the same family, such as is needed to prove satisfactorily the occurrence of heredity.

In Mr. Clinton Dent's case of osteomalacia,[25] commencing in a male, aged four months, which has already been referred to as an instance of degenerative hypoplasia of bone, there are indications of some hereditary tendency to the complaint. "The parents were healthy but a sister had curvature of the spine; one cousin suffered from the same condition as the patient, another had scoliosis, and a third cleft palate." Here we have not only the statement of family heredity but also evidences of association with an hereditary deformity, constituting indirect heredity.

In an instance given by Ekmann[26] the disease began in a great-grandfather whose limbs were so deformed that he could not walk. Children of the succeeding generation were affected with deformity and softening of the bones, and of the next two generations with bending and fractures. Although there are points about these cases which are greatly in favour of their being examples of osteopsathyrosis, yet it is right to say that Ziemssen is of opinion that they may be due to rickets.

In the report of a case of osteitis deformans by Dr. Stephen Mackenzie[27] it is stated that "the patient was one of twins; his twin brother was imbecile and died in early life in an asylum. Dr. Robinson (who attended him at the time of death) elicited the important information that an

elder brother died a few years before the patient, at the age of 52, crippled by a deformity of his lower limbs. The course of his illness resembled that of the present case and he was believed by his family to have the same disease."

Another instance is given by Mr. Lunn.[28] The patient had a brother who was said to have died from cancer, and another brother, aged 68 years, who was examined by Mr. Lunn. Mr. Lunn says: "He tells me that he has noticed his own head getting larger and his hat seems too tight for his head. I find both femora enlarged in their lower halves and the right clavicle is decidedly larger than the left." Mr. Bryant[29] says that one of the five cases originally published by Sir James Paget had been that of a patient of his own and that he had the opportunity of following out the case to the end. He survived the publication of his case for 10 or 12 years. Two brothers who are still living are beginning to show signs of the same disease. Of this family these were the only three members.

8. Both diseases have their physiological bases in certain changes of normal growth. These changes are chiefly of two kinds, according to whether they are produced by sex or by age.

(*a*) Changes produced by sex.—Osteomalacia is, as a rule, disease of women and osteitis deformans is a disease of men. This is best explained on the ground that they are vices of growth and are therefore more liable to select those parts in which normal growth is most vigorous. Women are of the more passive or "lymphatic" temperament. The tendency of their tissues is rather towards the formation of fat and of lymphatic tissue than of muscle and bone. It is probable that the lymphoid tissue of the bone marrow is relatively of better growth in women than in men; it is also more subject to growth disturbance. The healthy rise and fall of nutrition which takes place periodically or at uncertain intervals renders it more liable to that loss of equilibrium which constitutes disease. On the other hand, there can be no doubt that the hard tissue of the skeleton of a woman is relatively of inferior growth; her bones are shorter, weaker, and slighter than are those of a man. Hence it is but to be expected that women should be more liable to false hypertrophy of the marrow and men of the hard substance of their bones. All this indicates that the respective pathological conditions have in each case a physiological antecedent and that this varies with the sex. This connexion between the sexual organs and the skeleton is so important in its bearing on the pathology of osteomalacia that it is necessary to deal with it more fully. It is shown under natural conditions as follows. 1. The growth of the sexual organs at puberty is closely associated with the growth of osseous tissue. The change of life which takes place at this age is almost as much one of the skeleton as of the reproductive organs. It is true that there is at the same time increased activity of growth of the soft parts, but this is slower than the growth of the skeleton and appears to be secondary to it as the result of physiological adaptation. The youth of 16 years of age is, as a rule, obviously more bony than the young man of 20, but it is not until the age of 25 years or thereabouts is reached that the muscles attain their full development and the soft parts reach to the standard of the skeleton. 2. A connexion between these organs is also to be observed during the decline of life, especially in women. The menopause corresponds in point of time with the period of physiological degeneration of the marrow. 3. It has been noticed that the bones and red marrow become more vascular during pregnancy, while the marrow is increased in amount. After pregnancy is over they return to the ordinary state.[30] This association is still more evident in certain abnormal conditions. 4. Premature sexual development is prone to bring with it corresponding changes in the bones. Thus a girl in whom menstruation has commenced prematurely may rapidly acquire the figure, and almost the height, of the mature woman. In a case of this kind I have observed that the ossification of a child of three years, shown in a skiagram of the hand and adjacent part of the forearm, corresponded with that of a normal child of 12 years. Similar changes may take place in the male. 5. On the other hand, absence of sexual organs in the young male determines a condition of bone growth which approaches that of the female; and absence of ovaries in the female is associated with a condition which approximates to that of a child. In all these instances it is evident that there is close relation between the bones and the sexual organs, though it is shown in different way in different cases. 6. Of the same significance is the fact that the bones of the female which are involved first and most frequently in osteomalacia are the pelvic bones, whereas in the male there appears to be no such selection, these bones not having the same sexual significance that they have in the female.

This connexion between bone and sexual organs is quite sufficient to account for the relation of osteomalacia to the functions of the ovaries without seeking for any other cause. The process which gives rise to degenerative hyperplasia is essentially a growth excess. It is a hypertrophy affecting a part which is undergoing degeneration and leads in consequence to overgrowth, but not to increase of function. Anything therefore which will tend to promote the activity of the red marrow will favour the onset and progress of the disease. In healthy pregnancy there is a general rise of nutrition, in which the bones share. This is the time when osteomalacia is most likely to appear, and the ossa innominata of parturient women, inasmuch as they are most active at this time, are the bones most likely to be affected first. On the other hand, there is, as a rule, a subsidence of activity during the period which immediately follows childbirth, and this is the period during which osteomalacia usually abates. Similar, though less marked, fluctuations are often produced by menstruation, which in some respects is a miniature childbirth. All these facts tend to the conclusion that whatever excites the activity of the red marrow promotes the disease, and that whatever depresses the function of the red marrow tends to subdue the disease. At the same time it is most improbable that osteomalacia is the direct result of increased nutrition. It is far more likely that owing to premature degeneration of the marrow, or to some general depression of vitality, it is unable to react to the calls which are made upon it during pregnancy, and the attempt to do so results, not in true hypertrophy, but in the spurious hypertrophy of osteomalacia. Thus, while it may be true that undue accesses of general nutrition precipitate the onset of the disease while the return to equilibrium improves it, the first cause may be traced to depressing influences alone. It is on these lines that we must look for the explanation of the immense improvement which so often takes place after the removal of the ovaries in cases of osteomalacia. There is no occasion whatever to look for some chemical solvent, some peculiarity in ovarian structure, or for fungi as an explanation of what is so amply accounted for. It is most improbable that a disease should be so strikingly influenced by such a physiological catastrophe as deprivation of the ovaries unless the disease and the catastrophe were intimately bound up together. In other words, the nature of both cause and effect plainly indicates that in *both* cases there is some very direct interference with physiological processes. Nothing is better calculated to show, on the one hand, that osteomalacia is an affection of growth and, on the other hand, that it is brought about by some influence which is internal, primary, or essential and is not dependent upon any outside cause. Osteitis deformans is probably not obviously affected by these sexual changes, partly because of the greater stability of bone as compared with bone marrow, and partly because it ordinarily appears at an age when the sexual organs are extinct.

(*b*) Changes produced by age.—The changes which take place both in osteomalacia and osteitis deformans are in many respects much like those which are met with in the marrow and bone of the aged. But the resemblance is one of kind rather than of degree. It is, in fact, so grossly exaggerated as to be a caricature rather than a resemblance. It is such as we may imagine would result were senile degeneration to become an active instead of remaining a passive process. In the natural course of events the red marrow undergoes fatty degeneration into yellow marrow and so it remains or becomes gradually absorbed. But in osteomalacia degeneration takes place far more rapidly and is met by wild and misdirected attempts at repair. The new material which is so lavishly expended is either incapable of transformation into proper red marrow or itself undergoes degeneration and so does but add to the mischief. The process is suggestive of a senile degeneration taking place in one organ, while the rest of the body is still vigorous and in a condition to resent a premature decay of part of its community. The changes which take place in health are retrogressive, whereas in osteomalacia they are also progressive. They are retrogressive in quality and progressive in quantity.

[29] THE LANCET, May 31st, 1890, p. 1182.
[30] Hanau: Festschrift der Medicin, 1892, No. 7.

Much the same may be said of osteitis deformans. Professor Sir G. M. Humphry has taught us that senile changes in bone may be expressed by overgrowth as well as by atrophy. The porous bone of osteitis deformans is, it is true, very different from the dense layers of bone which are sometimes laid down in the calvarium in healthy old age. But it is not difficult to imagine that if to a deposit of fresh bone and to normal atrophy there be added the active process of interstitial embryonic cell-growth all the changes of osteitis deformans may be accounted for. This cell-growth has the same effect that yeast has upon dough: it makes the bone lighter, coarser, and bulkier. Osteitis deformans is like a redundant, senile osteoporosis. The grosser appearances of osteitis deformans are also those of exaggerated old age. The bent back, drooping figure, and bowed head of a patient affected with this disease are strikingly senile, and so are the shuffling gait and that loss of vigour and elasticity of carriage which is so characteristic of the disease. Finally, we have the increased liability to malignant degeneration which has already been commented upon.

CONCLUSION.

Enough has been said to show that the four primary growth diseases—hypoplasia, hypertrophy, degenerative hypoplasia, and degenerative hyperplasia—are all represented in the skeleton. They form two divisions of which the one—hypoplasia and hypertrophy—is distinguished by mere defect or excess of normal growth; while the other, in which are comprised the two degenerative diseases, shows all those broad clinical and anatomical features which in the first part of this article were seen to be characteristic of the degenerative diseases of growth, whatever the tissue may be that they effect. And as degenerative hypoplasia of the skeleton is seen to run into degenerative hyperplasia by imperceptible gradations, each being distinguished from the other by characters imprinted by age alone, so degenerative hyperplasia is subdivided into two diseases according to tissue. If it affects the hard substance of the skeleton especially it is called osteitis deformans; if the soft substance it is called osteomalacia. As a rule these two diseases are well defined, though in all cases both the clinical and material characters of the one can be traced in the other. The differences between them are in the main due to differences in tissue, function, sex, and age alone. They are due to variations of the part affected and not of the affection itself.

What has been said of the skeleton and its growth diseases may also be said in effect of all other tissues and their growth diseases. All are liable to the same four kinds of disorders and all are affected in the same way, varying only to the extent that one tissue differs from another tissue, one time of life from another time of life, one function from another function, and one sex from the other sex.

A CASE OF SYPHILITIC FIBRO-SPONGIOID OSTEITIS.

BY J. BASIL HALL, M.C. CANTAB., F.R.C.S. EDIN.,
SURGEON TO THE BRADFORD UNION HOSPITAL.

ALTHOUGH Wegner, Parrot, and Barlow have established the fact that in cases of inherited syphilis the bones are very frequently affected, it is remarkable how seldom such conditions are recorded in this country. The syphilitic pseudo-paralysis consequent upon epiphysitis is occasionally seen in the out-patient rooms of hospitals, but those forms of disease which Parrot has classed under the generic name "osteophytic" seem to be rarely observed. Possibly this may be due to the fact that the less marked cases never apply for treatment, whilst in others bending of the bones and other changes produce an appearance very similar to that of rickets, for which the disease is consequently mistaken. The case which I here record was sent into the hospital as rickets with a view to osteotomy.

A boy, aged 14 years, was admitted into the Bradford Union Hospital on Sept. 8th, 1899, with deformity of the legs. His family history was as follows. His mother had been twice married, and by her first husband she had had one daughter who was healthy and who was now grown up. Her second husband was a steady and temperate man but was very delicate. By him she had had five children, of whom the patient was the eldest. The second and third children died in infancy and the fourth and fifth were stillborn. The mother stated that the patient had snuffles very badly as an infant, that he was a very sickly child, and that he did not walk until he was five years old. He had had no rash at any

From a photograph showing enlargement and curvature of the tibiæ, especially of middle segment.

time except measles. She noticed bending of the legs about 18 months after he began to walk. As regards his condition on admission to the hospital the patient was a sleepy-looking boy and obviously was suffering from adenoids. He walked with a curious gait as if his legs were too heavy for him. He complained of aching pain in the legs at night, especially in the right leg. There was marked asymmetry of the skull, the left parietal and frontal region appearing to be flattened, whilst on the right side a large boss on the frontal bone made the temple singularly prominent. The skull was of the dolichocephalic type. The bridge of the nose was slightly flattened, whilst the malar bones felt more massive than normal. The teeth were very irregular and several were ill-developed. The incisors were tapering and pointed, but there was no central notch. The arch of the palate was excessively high and narrow. The lower jaw was greatly thickened, especially on the left side, where the enlargement could be seen on the face. The thickening of the bone was irregular, so that the surface felt smoothly undulating. On the right side there were three distinct bosses, but on the left the greater degree of thickening was nearly uniform from the angle of the jaw to the symphysis. The thyroid gland was large, the outlines being quite evident to the eye. Both clavicles were much thickened in their inner half, especially the right, the enlargement of the latter being distinctly visible in spite of the boy being fairly fat. The right humerus was irregularly thickened in its lower third, but the left was normal. There was no rickety enlargement at the wrists. The hands and nails were normal. The chest was well developed and was of good proportions. There was no beading of the ribs or

any sign of rickets. The body generally was well nourished. The spine was normal, as also were the pelvis and femora. Both tibiæ were greatly enlarged and appeared to be much elongated in proportion to the rest of the limb. The right tibia was from half an inch to three-quarters of an inch longer than the left. They both presented an anterior convex curve in the middle two-fourths. The lower fourth was normal in shape. These bones, whilst they were generally enlarged to a very marked degree, had in addition irregular bossy swellings on their surface. These bosses were not prominent but were sufficiently marked to give the surface of the bone a smoothly undulating character. A quantity of softer tissue surrounding the bone and filling up the interosseous space was also felt, as if there were great thickening of the periosteum. The cutaneous veins were large and prominent. There was slight tenderness on pressure, especially of the right leg, and the boy flinched when the limb was grasped firmly. To summarise, therefore, there had been osteitis in the lower jaw, in the clavicles, in the right humerus, and in both tibiæ. There was asymmetry of the skull with thickening of the right frontal bone and possibly some slight thickening of the malar bones.

Parrot describes two osteophytic forms of bone affection in congenital syphilis—viz., the osteoid form and the fibro-spongioid or rachitic form. The osteoid form may develop at any period of childhood and may possibly even be prenatal. It consists of osteoid growths of a pinkish colour with trabeculæ arranged perpendicularly to the surface of the bone. The tissue is more brittle than normal bone and contains large quantities of lime salts. The trabeculæ are separated from each other by medullary tissue. The fibro-spongioid variety, on the other hand, never appears before the fifth month of life. It begins as a sub-periosteal growth of yellowish pearly fibroid material over which the periosteum is much thickened and closely adherent to it. It may attain as much as half an inch in thickness and is very vascular. There is always a distinct line of demarcation between the new tissue and the bone beneath. The bones most commonly affected are the humerus at its lower end, the ulna, the femur, and the tibia. Although two distinct forms are thus described by Parrot, both are usually present together in varying degree, the osteoid tissue being covered by a layer of the fibro-spongioid material. In the case under consideration there seems to be an arrangement of this kind, the enlarged bone with its smooth nodes feeling as if it were clothed with a softer material of considerable thickness. The abnormal vascularity shown by the enlarged cutaneous veins also suggests this view.

The illustration shows very well the enlargement of the limbs and the degree of bending. It is worthy of note that the convex curve of the tibiæ occupies a different position to that commonly seen in rickets, being confined to the middle segment rather than the lower segment of the bone—a point of some practical importance in the differential diagnosis in a less marked case. This deformity was called attention to by Fournier, who described the curve of the bones as "sabre-shaped." Profile skiagrams of the tibia show the great thickening and the curve of the bone, whilst one of both bones taken from the anterior aspect delineates the osteoid node formation at some points.

Clinically speaking the most striking feature in the case is the marked clumsiness of the lower limbs. The patient walks as if he had heavy weights attached to his feet. The legs appear to be too long below the knee so that in bringing the feet forward he has to trail them on the ground. The family history is peculiar in that it is a typical syphilitic one in reversed order, but in spite of the absence of a definite proof of inherited disease I think no one would doubt the nature of the case for one moment.

Parrot[1] has fully described the osseous lesions occurring in congenital syphilis and in 1879 he gave an address on the subject to the Pathological Society of London and exhibited a large number of specimens. The interest aroused by his investigations seems to have chiefly centred on cranio-tabes and the conditions which give rise to the "natiform skull." Beyond Parrot's descriptions little seems to have been recorded, and I have been unable to find any account in English literature of such a pronounced type of the disease as in the case here related. Moreover, so far as I can ascertain, there is no report of any case in which the lower jaw has been involved. Affection of the clavicles has been observed in rare instances, but as a rule the lesions have been confined to the bones of the leg and the humerus. There can, I think, be little doubt that the bone lesions in inherited syphilis very frequently escape observation, otherwise it is difficult to explain the assertion of various writers that, excepting only the skin, the bones are more commonly affected than any other tissue. Such a marked example as the one here recorded is certainly uncommon, and is worthy of record if only to draw a closer attention to these conditions.

Bradford.

REMARKS ON THE VALUE OF UROTROPIN AND ITS PRACTICAL APPLICATION AS A URINARY ANTISEPTIC.

BY H. E. DRAKE-BROCKMAN, F.R.C.S. EDIN.,
CAPTAIN, INDIAN MEDICAL SERVICE; AGENCY SURGEON AT BHARATPUR, RAJPUTANA.

THE drug urotropin, or "aminoform" as it is sometimes called, appears hitherto to have attracted little or no general attention, at any rate in this country, but there is little doubt nevertheless that in it we possess a most efficient urinary antiseptic. A clinical experience of over two years in the use of this drug enables me to add my testimony to its efficacy as a urinary antiseptic, but besides this action it has other important therapeutic properties which must not be overlooked, and may briefly be summarised as follows: (1) as a urinary antiseptic; (2) as a uric acid solvent; and (3) as a mild, non-toxic, and therefore harmless diuretic.

As regards the exact mode of its action as an antiseptic there appears to be some difference of opinion, but considering its chemical composition (the drug being a derivative of formic aldehyde and due to the combination of ammonia with formaldehyde) it is more than probable that its action as an antiseptic is, in part at any rate, attributable to the evolution of free formaldehyde in the urine, though all of the drug is probably not decomposed into formaldehyde. This may be readily verified from the fact that the drug itself may be detected in the urine within half an hour of its administration by the addition of a few drops of liquor bromi to it, when a reddish precipitate (urotropin bromide) will appear, showing how rapidly the drug is eliminated from the body in a more or less unaltered form.

It has been stated by one observer (and on this point my own clinical experience agrees with the statement) that one condition necessary for its complete action as a urinary antiseptic is that the urine should, if possible, be acid in reaction. This, coupled with the fact that the drug when heated with mineral acids gives off formaldehyde, tends, I should say, to favour the theory that its antiseptic action is attributable, more or less, to the presence of free formaldehyde. The latter, after administration of the drug per os, has been detected always in the urine, and sometimes in the blood also, which tends to show rather that the change takes place, at any rate in part, before the drug could ever have reached the urinary tract, or come into contact with the urinary secretion. It is just possible, however, that some obscure changes do take place within the body which enable it to exert its action fully as an antiseptic—changes, perhaps not yet thoroughly understood by us and which do not, at any rate, fall within the limits of this paper, but rather within the domain of the chemist.

Firstly, with reference to its action as a urinary antiseptic urotropin can be used with success in any condition involving invasion of the bladder or urinary tract by pathogenic micro-organisms. Foremost amongst these pathological conditions cystitis may be reckoned, whether primary or secondary to enlarged prostate or vesical calculus, &c. All of these conditions directly render the urine septic, which under the circumstances, moreover, acts as a most efficient medium for the development of these pathogenic micro-organisms once infection has taken place. In all such cases this drug usually gives speedy relief. Under this head I may mention its use as a preliminary to operations connected with the bladder or urethra, but more especially with reference to litholopaxy. In this case I have made it more or less a routine in my practice to administer the drug a day

or two previously to operation, when its speedy action, especially in India, is a decided benefit to patients who cannot, and do not usually like to, stay longer in hospital than necessary in order to render the urine as aseptic as possible, as there is usually a certain amount of cystitis present in most cases of vesical calculus before operation. I have good reason to believe that in one case at least upon which I operated—one of vesical calculus of large dimensions associated with enlarged prostate—in which there was marked concomitant cystitis, the patient's early and complete recovery was directly attributable to the preliminary use of the drug in this manner. Its employment possibly prevented the further development of septic micro-organisms within the bladder and thereby lessened the risk of any of these travelling backwards up the ureters and ultimately finding their way to the kidneys and setting up septic infection there, inducing pyelitis, &c., which complications may so easily ensue after such operations. Further, under this head I may also mention the important use that this drug may be put to in rendering aseptic the urine of patients suffering from enteric fever or other diseases in which it is known that pathogenic micro-organisms are eliminated from the body by this channel. There is little doubt that this occurs in diseases other than enteric fever; for instance, it is known that the bacterium coli commune is frequently found in the urine, and when present there plays a prominent part in the production of cystitis, possibly in the course of its elimination from the body in this way. It is now a well-established fact that the urine of patients suffering from enteric fever, more especially after the second week of the disease and during convalescence, contains large numbers of the bacillus typhosus. It is therefore important thoroughly to disinfect the liquid excreta of such patients as well as their fæcal evacuations. The use of urotropin in such cases should prove invaluable in preventing the dissemination of enteric fever by this important, and, I fear, much overlooked, channel of infection. It is obvious that, if possible, the urine should be disinfected before its evacuation from the bladder, rather than that this process should be left till afterwards, possibly to be forgotten altogether. This point is of very great importance in India and in tropical countries, where the means employed for the disposal of excreta are usually some form of dry earth system. That this is not always under the strictest supervision must be within the cognisance of those medical men who have practised in India, where liquid excreta are often carelessly disposed of by being thrown broadcast over the surface of the soil without previous disinfection. The risk is undoubtedly increased in the case of enteric fever affecting native patients, whose ideas of sanitation as well as of decency are usually very crude, and who, as a consequence, micturate as well as defecate indiscriminately over the surface soil, anywhere and everywhere. It is easy to conceive that when the soil is dry, and hot winds blow, or a dust-storm occurs, that the bacilli as well as the spores of pathogenic microbes (where such occur, which, however, is not the case, of course, with the bacillus typhosus) are carried far and wide, and that they eventually find their way into some well or other source of human food or drink supply with disastrous results. In India, it may be remarked, wells are usually of the open, and therefore unprotected, kind. There is little doubt in my mind that the subject of the thorough disinfection of the urine of patients suffering from enteric fever, previously to its final disposal, has not hitherto generally at our hands received the notice that it deserves. At any rate, as regards India in particular, I feel sure that enteric fever is spread more by means of this than by almost any other agency. Moreover, I fancy that when the medical history of the war in South Africa, especially with reference to the prevalence of enteric fever amongst the troops, comes to be written, it will go far to prove the truth of my statement. It was conclusively shown by one observer, as a result of some very interesting experiments made by him to determine the microbic impurity of the air of inhabited dwellings, that the number of microbes present per cubic foot of air was directly in proportion to the amount of dust particles floating about in the air of the space experimented upon, proving that dust is one most important agency by which microbes are disseminated. The particular case to which I refer was that of a school in which large numbers of children were accommodated. If the prevalence of dust everywhere (more especially in tropical countries, where it is blown far and wide by means of hot winds and dust-storms) be taken into account it may be imagined that a very important part is played by it in the dissemination of pathogenic micro-organisms of all kinds. That being so, we cannot exercise too much trouble and care in the execution of measures for the complete and effectual disinfection of all excreta, urinary as well as fæcal. It is in such cases that I see a wide and successful field for the employment of a drug such as urotropin, by means of which we are enabled to check the growth—in fact, to destroy the vitality—of pathogenic micro-organisms of all kinds within the body and before their evacuation, at any rate, by such a channel as the urinary tract. Under the head of a urinary antiseptic also, urotropin should prove of great value in the treatment of gonorrhœa, gleet, &c.—in fact, in any form of urethritis of microbic origin.

Secondly, as regards the action of urotropin as a solvent of uric acid, I have given it with benefit in cases of gout, gravel, and uric acid diathesis, and when combined with salicylic acid in certain cases its action is rendered more potent still. With reference to its action as a solvent of calculi, I fear for obvious reasons that we cannot hope that it will in any way replace surgical interference. I do not doubt, however, owing to its capability of rendering alkaline urine acid, and aided by its antiseptic properties which retard the growth of the bacteria of ammoniacal decomposition, that it may possibly prevent the growth of calculi already in the bladder, by lessening the chance of phosphatic deposits taking place. These phosphatic deposits usually occur sooner or later if left alone. In order to test its value in this matter I made some experiments on a small scale with the drug *in vitro*. Small portions of uric acid were taken from fragments of a calculus removed previously by litholopaxy. These were exposed to the action of a concentrated solution of the drug in pure and freshly sterilised water. The solution was then placed in an incubator and kept at body heat for some days, after which time I could not detect any appreciable loss of weight or substance. This result goes rather to prove that when a calculus, even of uric acid formation, has already formed, we cannot look to much permanent benefit from the exhibition of this drug, though it is just possible that in the presence of normal urine its solvent action would have been more pronounced. Stress of work and my having to proceed on sick furlough, however, prevented me from going more into this matter then, and I fancy that its solvent action on uric acid depends upon other complex chemical changes during its passage through the body, which probably operate upon this product through the medium of the blood and not locally. This is a subject which I hope to go into on my return to India.

Thirdly, with reference to its therapeutic action as a diuretic, an effect which is distinctly beneficial as a secondary help to its antiseptic action, it occasionally causes slight purging. This I noticed particularly in one case of enlarged prostate with irritable bladder in which I gave the drug. The amount given need not exceed 30 grains per diem, and it forms an agreeable, almost tasteless, beverage when taken with a little aerated water. I have myself hitherto seen no untoward results from its administration, but I believe that when the drug has been given in excess it has caused unpleasant symptoms, such as distressing diuresis and pain in the bladder and urethra, accompanied with slight hæmaturia, all of which symptoms, however, have at once ceased on the suspension of the drug or diminution of its dose, no permanent injury resulting.

In conclusion, I feel sure that there is a very wide field of usefulness in the future for the employment of urotropin. It has hardly, I think, received sufficient notice hitherto from the profession in England, but I am confident that its claims will be readily taken into account when it comes to be more generally known. In the hope of such a result I am glad to be able to add my testimony to its worth as a valuable therapeutic agent for combating a troublesome class of cases.

DRAINAGE OF EGG-BUCKLAND.—At Plymouth County Court on June 20th a dairyman claimed £20 from the Plympton Rural District Council for damage to a field at Egg-Buckland by reason of defective drainage. Evidence showed that the council without any notice to the plaintiff laid a drain through the field to a cesspit at the top, the result being that the cesspit constantly overflowed. The plaintiff was awarded 12 guineas and costs.

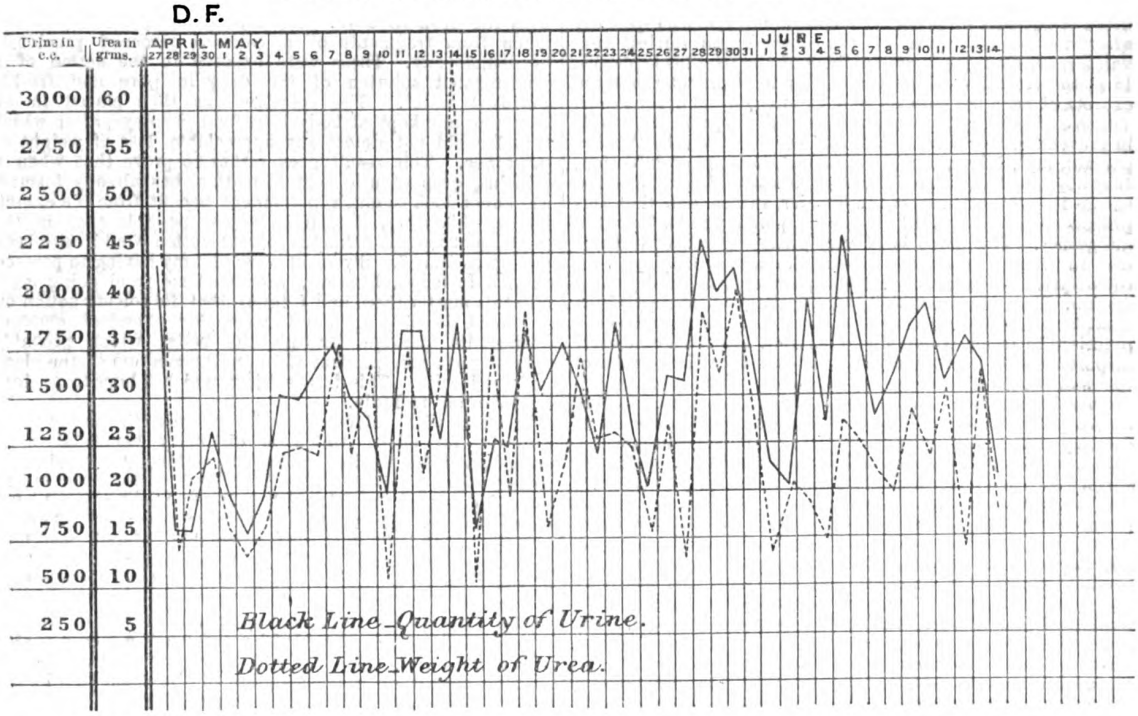
THE EXCRETION OF URINARY WATER AND UREA FROM THE HUMAN BODY, WITH DIMINISHED KIDNEY WEIGHT.[1]

BY JOHN B. NASH, M.D., M.R.C.S.,
HONORARY SURGEON TO THE WALLSEND HOSPITAL, NEW SOUTH WALES, ETC.

THE subject matter for this paper was suggested by a study of lectures published in THE LANCET of March 19th and 26th, and of April 2nd, 1898. They were entitled "Observations on the Pathology of the Kidneys," by Dr. John Rose Bradford, Professor Superintendent of the Brown Institution. As there were three patients in my practice with kidney weight diminished it occurred to me that an estimation of the quantity of urine and of its nitrogenous constituents excreted in a period extending over several weeks might be of sufficient interest to make a suitable contribution to this section of the congress; and it would apply to the human individual the principles laid down in the lectures quoted, and also contribute somewhat to our knowledge of the behaviour of the kidney tissue when its total weight relative to the rest of the body is diminished. In two of the cases one kidney—i.e., one half of the total kidney weight—and in the third slightly less than one fourth of the total kidney weight had been removed. The following are the cases.

CASE 1.—The patient was a female, aged 35 years. On March 24th, 1896, the right kidney was removed. On March 16th, 1899, she was confined of a full-sized healthy male child. The estimations were made about three years after the operation and at the time she was suckling her infant. They were begun on April 27th, 1899, and they were continued daily to June 14th, a period of exactly seven weeks.

CASE 2.—The patient was a male, aged 20 years. On May 29th, 1897, slightly less than one half of the right kidney was removed. The estimations, extending over a period of 52 days, were made two years after the operation they were begun on April 24th and ended on June 14th, 1899.



CASE 3.—The patient was a female, aged 56 years. On April 22nd, 1899, the left kidney was removed. The estimations were begun on the day after the operation and they were continued for 53 days or up to June 14th, 1899.

Cases 1 and 2 had time to settle into the normal condition and they exhibit the behaviour of diminished weight of renal tissue in bodies that had assumed a normal standard after complete recovery from the affections for which they were treated. There is one apparent difference in that the first patient suffered from disease and the second met with an accident; this is of no moment as the excreting tissue *in corpore* in each case must have been of a healthy type. Both individuals were upon an ordinary mixed diet and they carried on their customary duties. Case 3 shows the behaviour of one kidney immediately after it had been deprived of the assistance of its fellow, in which slightly more than half the acting structure was capable of performing its function, and further it shows how this single organ was equal to the requirements of the rest of the tissues in passing away the necessary quantity of water, nitrogenous extractives, and other solids after a somewhat serious operation.

In all the three cases the specimens examined were taken from the mixture of the total amount collected daily. The standards of comparison used are those given in Campbell Black's "Urine and Urinary Analysis," edition 1895. Herein the quantity of fluid excreted by the kidneys in 24 hours is given as from 1000 to 1200 cubic centimetres in the female, and from 1400 to 1500 cubic centimetres in the male. The urea elimination is stated at about 25 grammes daily in the female and from 18 to 30 grammes daily in the male. The volumetric analysis of the urea was made by the hypobromite of soda process with the ureometer of Doremus.

That one kidney is capable of doing the scavenging for which two are generally provided has been demonstrated upon many occasions in the after-history of persons from whom one kidney had been excised. The more thoroughly we realise the capacity of a diminished weight of tissue to perform all the particular requisite functions of the body which it was ordained to fulfil, with the more self-satisfaction do we attack and remove a diseased area of this tissue. The experiments in the dog (and they are being found to

CHART SHOWING EXCRETION OF URINE AND UREA IN CASE 1.

[1] A paper read before the Medical Section of the Intercolonial Medical Congress held at Brisbane in September, 1899.

apply to the human individual) have thrown much light on the physiology and pathology of the kidney; with the function of the healthy organ as an excreting tissue in some of its relations this paper is intended to deal.

Professor J. Rose Bradford writes: "An animal (dog) with diminished kidney weight is unable to excrete a concentrated urine ..... the urea is eliminated by an increased flow of water occurring—i.e., an hydruria follows; in this way the larger amount of urea is got rid of without the percentage in the fluid being greater. In a normal animal the urea is got rid of by the urine containing a greater percentage of it."

In Case 1 in the seven weeks during which the daily estimations were made the highest concentration was 3·47 per cent. of urea once, 2·8 per cent. once, and 2·79 per cent. once; the daily average throughout the whole period was 1520·5 cubic centimetres of urine containing 1·6 per cent. of urea; this is comparable to the 2·05 to 2·5 per cent. which is the approximate proportion excreted in the healthy female with two kidneys. The one kidney in this woman is able to excrete urine in all ways similar to that which we find in a normal woman. The highest proportion, 3·47 per cent., is sometimes demanded of the kidneys in the average healthy female with variations in diet, and upon the particular day of this excess there was a relative hydruria, 1875·5 cubic centimetres of urine having been voided. The greatest quantity of fluid that was passed in any one day was on two occasions 2301·7 cubic centimetres with urea 1·89 and 1·19 per cent. respectively. (See table, Case 1, and chart.)

In Case 2 during the 52 days over which the estimations extended the highest concentration was 3·59 per cent. of urea, with an excretion of 937 cubic centimetres of urine. On 15 occasions the proportion was over 2·25 per cent., while for the whole period the average quantities daily were 1167 cubic centimetres of urine and 2·13 per cent. of urea. This would seem to indicate that the kidney

and one half passed away a sufficiency of nitrogenous material but that there was a slight deficiency in the quantity of fluid. That the renal tissue left was capable of passing away more than an average daily amount of urine is evident, as 1506, 1534, 1591, and 1648 cubic centimetres were voided on four of the days. There was no marked hydruria or polyuria. (See table, Case 2.)

In Case 3 in the second and third 24 hours after the operation the highest concentration of the urine was seen, the single kidney excreting a fluid with 4·56 per cent. of urea. Moreover, the largest quantity of urea excreted during any one day was 29·8 grammes, and that in the second 24 hours after the operation with urinary water 653·5 cubic centimetres; in the third diurnal period 28·3 grammes, with 625 cubic centimetres of water; in the following like time 27·5 grammes, with 653 cubic centimetres of water. On the fiftieth, fifty-first, fifty-second, and fifty-third days the quantity of urine voided was respectively 1676, 1562, 1428, and 1335 cubic centimetres, with 0·79, 0·90, 1·02, and 1·49 per cent. of urea. The average for the 53 days was 889 cubic centimetres of urine, with 14·1 grammes of urea, or 1·57 per cent. The quantity of fluid voided steadily increased and towards the end of the estimations there was practically a hydruria but not a polyuria. (See table, Case 3.)

In Case 1 a great variation between the minimum and maximum quantities in both urine and urea is to be seen. Under 800 cubic centimetres of urine were voided on four days, while over 2000 cubic centimetres were passed on five days. During the whole period the average 1520 cubic centimetres per day is well over the quantity voided daily by a healthy woman with two kidneys. Compared with the two other cases the urea variations were remarkable; more than 59 grammes were excreted on two occasions, the highest being 65·2 grammes on the eighteenth day of the estimations. Under 13 grammes were produced three times. These figures show that the single kidney is capable of getting rid of twice as much water and three times as much urea in one day as is the average for two healthy kidneys. The woman was in perfect health on an average mixed diet and suckling a full-sized male child.

In Case 2 the patient with his one and one half kidneys *in situ* the urinary water was under 800 cubic centimetres per day twice and over 1400 cubic centimetres six times. For the whole period the daily average of 1167 cubic centimetres is about equal to what two healthy kidneys should excrete. The urea was below 14 grammes on two days and 33 grammes or over on seven days. Between these two limits the quantities varied considerably. The loss of one-fourth of his kidney weight did not materially alter the excretion of either the fluids or the solids by the renal tissue. The patient was a healthy young male, of average activity, living on a mixed diet. If estimations were made on a like man under similar circumstances, but possessing his full proportion of kidney weight, much the same variations would be found in the daily quantity of fluids and solids passed.

In Case 3 we have a condition like to the dogs of Professor Rose Bradford, as the estimations were begun immediately after the operation. He writes: "All partial nephrectomies, single or double, slight or extensive, increase the amount of urinary water, to different degrees it is true; the amount of urea is not increased by either single partial nephrectomy or by double partial nephrectomy or yet by the removal of one kidney and a portion of the other, provided always that at least one-third of the original total kidney weight be left to the animal." In Case 3 at no time during the first five weeks did the urinary water reach 1200 cubic centimetres in one 24 hours, the nearest to that amount being 1108 cubic centimetres passed on the thirty-fifth day. This does not agree with the hydruria found in the dog. The urea for the first 24 hours stood at the normal healthy average; during the second, third, and fourth daily periods it was about twice the normal amount per ounce of urinary water, but only a little above the total required to be excreted daily by a healthy female with two kidneys. This differs from what happened in Professor Bradford's dogs and shows that immediately after removal of one kidney in the human subject the kidney left *in corpore* is capable of excreting a somewhat concentrated urine. During the sixth and seventh weeks the urinary water voided kept well up to a healthy average, while on the four days of the eighth week the quantity was about 300 cubic centimetres above the average. In these same periods the urea was about one-half of that usually excreted by two healthy kidneys. The table as a whole shows a steady increase in the quantity of urinary water. At first, when this was small in amount, the patient had a low-tension pulse, she was unable to take much fluid wherewith to fill the blood-vessels, and a diminution in the filtering processes followed. After major operations there is usually wasting for the first few days; this is probably accompanied by an over-production of nitrogenous extractives in the tissues and blood, thence moving onwards to excretion through the kidneys. After the fourth day the urea fell to a normal degree and only five times during the subsequent analysis was it up to 19 grammes in the 24 hours. The patient put on flesh and soon regained more than her accustomed vigour.

In the *British Medical Journal* of July 29th, 1899, Dr. W. L. Bell of Lowestoft Hospital, England, reports a case of

abdominal nephrectomy for renal calculus. At the end of the article he writes: "Estimations of urine.—During the first 24 hours 14 ounces of highly albuminous urine were excreted, but after this it remained free from albumin, and during the second 24 hours there were 15 ounces, next three days 28 ounces each day, after which the amount passed generally varied from 35 to 45 ounces. Careful measurements extended over a period of eight weeks."[2] In further illustration of the cases forming this article a statement of weekly averages of urinary water and urea excreted are here shown.

The following conclusions appear to me to be justified: 1. If one kidney be removed then three years subsequently the healthy kidney *in situ* will excrete more than the average quantity of urinary water produced by two normal kidneys. 2. This same kidney will excrete per cubic centimetre of urine and per diem the average amount of urea that would be produced by two healthy kidneys. 3. If one half of one kidney be removed, then two years afterwards the urine voided will be the same in quantity as if two healthy kidneys were present. 4. The loss of the half of one kidney will cause no increase or diminution in the percentage of total amount of urea excreted. 5. If one kidney be removed then the quantity of urinary water excreted by the other during the seven weeks immediately succeeding the operation will be below the average daily amount. 6. The urea produced by this one kidney will be less than the average proportion usually seen as the result of the work of two healthy kidneys but probably not below the average excreted by two healthy kidneys from an individual recovering from a serious operation.

From the standpoint of the practical surgeon there is one important fact brought prominently forward in Professor Bradford's experiments and lectures. They teach us: first, that in the dog two-thirds of the total kidney weight can be removed with impunity, and the one-third remaining is consistent with the prolonged and healthy existence of the animal; and, secondly, that there is a limit between the one-third and the one-fourth of the total kidney weight beyond which, if excision be practised, the kidney tissue left is not sufficient for the sustaining of life, as the animal will rapidly emaciate and die; not, however, from uræmia, as even with one-tenth of the total kidney weight an hydruria and a polyuria immediately followed. Anyone of us may have the question brought before him in a case of kidney disease or a tumour growth of renal tissue as to how much of the kidney substance may be with safety excised. The general trend of all these observations is in the direction of Professor Rose Bradford's results, that one-third of the total kidney weight in the human being would be as capable of sustaining a prolonged and healthy life as he found to be the case in the dog. For the preparation of the accompanying chart and the working out of the averages and totals my best thanks are due to Dr. F. H. Cox, a graduate of the Sydney University.

Wallsend, New South Wales.

ON THE

USE OF MERCURY IN THE TREATMENT OF CARDIAC FAILURE DUE TO ARTERIO-SCLEROSIS.[1]

BY ALEXANDER MORISON, M.D., F.R.C.P. EDIN.,
PHYSICIAN TO OUT-PATIENTS AT THE GREAT NORTHERN CENTRAL HOSPITAL AND AT THE CHILDREN'S HOSPITAL, PADDINGTON-GREEN.

THE value of mercury in the treatment of disorders of the circulation was well recognised by the older physicians, but the zeal for its employment was not always according to knowledge. Consequently a generation arose which, following blindly in the footsteps of tradition and not finding their expectations answered, proceeded to ban mercury as a dangerous or useless drug under all circumstances and so impressed the public with this belated sagacity that even the acknowledged charlatan was forced to advertise his wares as free from that deleterious agent. One has only to mention the names of Withering and of Baillie, of Stokes and Graves and Gregory, however, to be certain that, whatever mistakes these distinguished men committed, they were the faults of strength, and that when they spoke positively of beneficial results obtained under certain circumstances they stated facts and opinions which required the respectful if discriminating attention of posterity. Posterity, however, for a time was more discriminating than respectful and it consigned in a great measure both these great authorities and their vaunted remedy to an unmerited oblivion. In the matter of mercury in the treatment of some forms of heart disease it is now beginning to revise its hasty condemnation.

It is not my intention on this occasion to consider the larger question of the use of mercury in the treatment of heart disease, but to limit myself to a consideration of its employment in that form of cardiac failure which is so frequently associated with the arterio-sclerotic changes connected with advancing life, and more particularly when this is coupled with that overwork for a means of livelihood which is the fate of many. I think I can do this most conveniently by quoting a specific instance and making it the peg on which to hang any general remarks I may have to offer.

A man, aged 67 years, an English labourer of the best type, calm, self-respecting, the father of a hard-working family and of good physique but stiff and bowed down with continuous work and advancing age, had been under my observation for about five years in the out-patient department of the Great Northern Central Hospital. He had suffered during that time from a tachycardial form of cardiac arrhythmia with periods of amelioration and comparative sense of well-being, broken by the inevitable relapse into breathlessness, defective sleep, and scanty urination, but never reaching that greater depth of cardiac failure associated with progressive anasarca and effusion into the serous cavities of the body until December, 1899. He then returned as an out-patient, water-logged and with a rapidly sinking heart. I advised him to enter the hospital, and by the courtesy of my colleague, Dr. E. Clifford Beale, he was placed under my care. By an oversight, however, I was not informed of his admission until a fortnight or so after that

[1] A paper read before the Æsculapian Society of London on May 19th, 1900.

event, during which time he was under the care of a house physician.

On admission into the hospital on Dec. 20th the patient's temperature is stated to have been 96° F. and his heart-pulse, so far as it could be counted with the stethoscope, 160, very irregular in force and in rhythm and few beats reaching the wrist. He was somewhat cyanosed and orthopnœic, and had a cough. He had anasarca as high as the waist and on his legs there were several foul sloughing sores. There was no detectable ascites and the urine was very scanty and contained some albumin. A mixture containing 15 minims of tincture of strophanthus, four minims of solution of strychnine, and 10 grains of diuretin was ordered to be taken every four hours. One grain of calomel was likewise prescribed daily, and at bedtime he took 20 grains of bromide of potassium and 20 grains of trional. Saline aperients were likewise administered and the patient was placed on admission diet. Ten days later there was no noteworthy improvement in his condition; the hypnotics were increased in power and tincture of digitalis was prescribed instead of tincture of strophanthus. On Jan. 5th, 1900, fish was added to the dietary and a pill containing two grains of calomel was ordered to be taken at bedtime every night. Finding on the 9th that the condition of the patient continued critical I placed him upon ordinary diet and prescribed three ounces of brandy, to be given in one-ounce doses and the last ounce at bedtime. I discontinued all hypnotics and ordered the pilula diuretica of the hospital pharmacopœia to be administered three times a day. This consists of powder of digitalis, powder of squills, blue pill, and extract of hyoscyamus, of each one grain. On the 16th the patient was still restless at night, but the œdema of his legs had subsided to some extent, and although there was a little recognisable serous effusion in his left chest, and the ratio between his heart and wrist pulse was as 150 to 100, the quantity of his urine had increased and it contained no albumin. By the 19th the ratio of his heart and wrist pulse was as 120 to 66; the impulse of the heart was stronger and its rhythm was regular; the patient slept better and there was less evidence of pleural effusion. The urine within the next few days began to flow more freely until on the 27th it reached a maximum of 110 ounces, and the patient's general condition had improved in every way. On the 31st the diuretic pill was discontinued as the patient's gums had become slightly affected. The urine, however, continued to flow satisfactorily until Feb. 12th, when it had fallen to 36 ounces, and on the next day the diuretic pill was resumed. Three days later it had reached 47 ounces and, with some fluctuation, a maximum of 73 ounces on the 19th. The general state of the patient had meanwhile continued to improve and on the 25th the pill was again omitted, and was resumed on March 3rd because of a fall of the urinary secretion to 15 ounces as nearly as could be calculated. Four days later the quantity had again risen to 50 ounces and the patient's general state was most satisfactory. All anasarca and serous effusion had disappeared, the force and rhythm of his heart had improved, and the discrepancy between the heart beat and the pulse at the wrist had been reduced, at times very greatly, such ratios as 90 to 72, 100 to 84, and 104 to 88 being noted. The patient also ate well, and slept from 7 to 10 out of the 24 hours without any other aid than his nightcap of one ounce of brandy. The diuretic pill was discontinued and again resumed for a few days at a time, and on the 27th the patient was discharged on account of the demand for beds. He was then in every way comfortable, and was free from all the evidences of cardiac failure with which he had been admitted. The heart, however, still manifested its arrhythmical instability and he was advised to rest as much as possible and to live as generously as his family could afford to allow him to do. He returned to my out-patient clinic in May free from œdema or subjective distress, but with increased tachycardial arrhythmia and stated that he could not "get along" without taking a few of his "pills" from time to time.

I have too great a regard for the reputation of mercury as a therapeutic agent in cases such as that just related to claim for it a greater share in the success attending its employment than an impartial review of the circumstances seems to justify. It has been pointed out alike by Baillie, by Stokes, and by others, that it is the combined operation of mercurials and cardiac stimulants which influences for good the majority of cases of cardiac failure such as that described. To these, however, must be added, in the case of persons in the circumstances of my patient, the rest, warmth, food, and general care which they receive on admission to a hospital. Without these influences it may safely be asserted that neither mercury nor digitalis would have had any result in the present instance. These, however, while they enabled the pill to act beneficially did not disprove the fact that there was an efficacy to be expected from the combination which would probably not have been attained by the use of one drug without the other, or, indeed, by the unduly preponderant use of digitalis as compared with the mercurial. For my present purpose it is fortunate that this point was also illustrated in this case. On admission a powerful cardiac stimulant and diuretic was prescribed, together with a grain of calomel separately at bedtime. A fortnight later, progress being unsatisfactory, digitalis was employed instead of strophanthus and an additional grain of calomel was prescribed to be taken at bedtime. It was not, indeed, until more than a fortnight after the simultaneous use of the drugs thrice repeated daily, and after the patient had been placed on full diet and brandy made to take the place of his ordinary hypnotics, that the full effects of the drug were attained and a urinary output which had fallen to 18 ounces and even 15 ounces a day rose to a maximum of 110 ounces. It could not, of course, be maintained at this high figure although such amounts as 93, 75, 81, 85, and 69 ounces were recorded. For it may be noticed in water-logged cardiac cases that when the methods employed begin effectually to squeeze the human sponge a copious drip takes place, but the human body obeys under the circumstances the general law of sponges which once squeezed fairly dry have little more than their normal moisture to part with unless they again become more or less water-logged, as may happen. As Carlyle was fond of remarking, "You cannot get more out of a thing than there is in it." Even under recurrences of anasarca, however, this case shows that a steady recourse to the combined drugs may again be expected to relieve the patient, and, as is stated at the conclusion of the record, the patient himself was so convinced of the value of his pill that he insisted on keeping it within reach. In his case I believe that he was justified in his confidence, although a like touching faith may be frequently observed under circumstances in which a wholesome scepticism would be more in place.

A few remarks may be made upon the possible causes of success in the treatment of the case related and upon the value of the combination employed. In connexion with the first point it is important to note that the kidneys of the patient, although congested, were essentially healthy, as it has been found by those who have used mercury in the treatment of heart disease that chronic renal disease, with the impeded elimination involved, is inimical to a sufficiently prolonged exhibition of the drug to secure beneficial action. In the next place all the agents in the compound pill prescribed were steadily pushed under favourable circumstances as to posture, food, and warmth until a definite result was secured. It is permissible to refer to this point because it is so frequently observed that a rational course of treatment has been conceived and initiated without being pushed home with sufficient persistence and vigour to secure success. In the third place, the patient was either philosophical enough or stupid enough to allow of the mental factor in his case being eliminated and thus prevented from upsetting the balance of his circulation by the intrusion of the emotions. Although the notes taken by the resident physician comprehensively state that while cardiac failure was at it worst the patient was "off his head" (as often happens under similar circumstances), he slept well and long when his anasarcous discomforts and the impediment in his circulation diminished and quite recovered his mental equilibrium. In sleep, while the vessels of the brain diminish in calibre the withdrawal of the psychical sphere from active operation appears to release the general vascular periphery, somatic and visceral, and thus to relieve the labour of the heart which, like the rest of the organism, enters refreshed on waking upon the work thrown upon it during the day.

The last point which may be mentioned as having conduced to the favourable issue of the case is that, although the patient was admitted to hospital on Dec. 20th, 1899, placed upon full diet and given systematic and persistent treatment by the diuretic pill and an allowance of brandy without hypnotics on Jan. 9th, 1900, and was practically convalescent towards the end of the same month, he was not discharged

from hospital until March 29th. In other words, he was two months in hospital under constant observation and with every comfort after convalescence was established. A similar case with equally happy results had been under my care in the hospital a year previously, and although this patient returned to the ward for a short time while the patient whose case I now describe was under treatment there has been no recurrence of his extensive dropsy since his convalescence. He also was kept for a long time in hospital. This patient was as old as the one whose case I now record, and had even harder arteries and a dilated and arrhythmical heart, and the full consolidation of his convalescence appeared to have established a compensation even under these circumstances which had successfully coped with the wear and tear of another year.

As regards the efficacy of mercury administered in the combination indicated and under the circumstances under consideration Sir Thomas Watson,[2] discussing the treatment of "anasarca," remarks: "Sometimes a combination or farrago of diuretic substances proves more efficacious than larger doses of any of the ingredients administered singly and the operation of some of these combinations is undoubtedly quickened or exalted in many instances by the addition of mercury. A fluid drachm of the officinal solution of the bichloride in each dose in a mixture or small quantities of calomel or of blue pill when the medicines are given in a solid form. A very useful pill of this kind, much recommended by the late Dr. Baillie, consists of three or four grains of the pilula hydrargyri, mixed up with one grain of the dried powder of squills, to be given twice or thrice a day. Dr. Baillie states that squills and digitalis are much less effectual by themselves than when combined with mercury." The formula of this pill, which is given in the second and third editions of Dr. George Gregory's "Elements of the Theory and Practice of Physic," is three grains of pilula hydrargyri and one each of powder of squills and of digitalis, to be taken at midday and in the evening. As the formula is not given in the first edition which was published in 1823—the year in which Matthew Baillie died—it is probable that the usual posthumous extension of Gregory's armamentarium took place after the death of his great and good contemporary. But Baillie would have been the first to acknowledge that the principle of the combination of coöperative elements was as old as the world itself, and exemplified by all the healing waters known to bathers and physicians from and prior to the days of the name-father of our society down to those of the last bath-doctor who has lost his mental equilibrium in enthusiastic praises of a new spring. Withering, indeed, writes of the therapeutic relation of squills to digitalis thus: "Next to the lancet, I think nothing lowers the tone of the system more effectually than the squill, and consequently it will always be proper in such cases to use the squill, for if that fail in its desired effect it is one of the best preparations to the adoption of the digitalis."[3] We now know that the active principle of squills acts much in the same manner as that of digitalis and that neither "lowers the tone of the system" except when administered in excessive doses or after too protracted use, but the above quotation shows that Withering's practical sagacity had detected the aid which one at times could lend the other. At page 170 of the same essay a prescription of Withering is given in which two grains of "grey mercury" were combined with 20 of powdered digitalis leaves and divided into 14 pills of which one was to be taken twice a day—evincing, surely, quite a modern timidity of mercury. I have not, however, met with any actual combination of all these ingredients in one pill in Withering's work and we may therefore assume that the attribution of that combination to the clinical acumen of Baillie is correct, but I have not so far met with a note of it in his works, which are well worthy of perusal even to-day. The addition of a grain of hyoscyamus —the "Guy's pill" used at the Great Northern Hospital— was probably not intended by its originator or originators to be other than a corrective to the intestinal effects of the other drugs, but it is just possible that as a drug of the belladonna group it may not be without influence upon the circulation when administered for a length of time. I have, indeed, occasionally used extract of belladonna in the pill instead of hyoscyamus on this principle and especially when there is a bradycardial rather than tachycardial tendency in the arrhythmia so frequently associated with arterio-sclerosis. The beneficial influence of mercury in the combination is, I think, clinically indisputable, but the discussion of the precise manner of its operation might lead to much, and perhaps not very useful, speculation. A fact, however, among the effects of mercurials to which Sir William Broadbent (to whom I attribute a considerable share in the revival of the medical use of mercury) attaches much importance is its lowering the tension of the pulse. How this is brought about—whether by the elimination from the blood of waste material which has a spastic effect upon the arterioles or by direct dilatation of the peripheral vessels in the process of its own elimination—it is not necessary at present to inquire and is very difficult to determine. That the permeability of peripheral vessels by a lessening of their resistance is secured appears to be clinically demonstrable. This being so it is not difficult to imagine, and is indeed permissible to suppose, that the combination of mercury (a peripheral dilatant) with digitalis and squills (which are in part central stimulants as well as peripheral contractors) constitutes it a rationally indicated adjuvant to the action of the latter in cardiac failure due to arterio-sclerosis. Like many other happy therapeutic combinations, however, it was probably at first employed in this connexion empirically, even by men of the calibre of Withering and of Matthew Baillie.

"THE ACTION OF THE WATER OF LLANGAMMARCH WELLS ON URIC ACID."

BY WILLIAM BLACK JONES, M.D., B.S. LOND., D.P.H.,
PHYSICIAN TO THE LLANGAMMARCH WELLS SPA.

IN an article under the above title which appeared in THE LANCET of March 25th, 1899 (p. 830), by Mr. Edward Russell and myself, we recorded observations on two cases, one of uric acid calculus and the other of lithæmia, in both of which the patients had derived considerable benefit from drinking the Llangammarch Wells mineral water. In the latter case (which was that of Mr. Russell himself) the amount of uric acid voided was estimated by Hopkins's method.

During the season of 1899 I had several cases of lithæmia under my care. All those that I have subjected to analysis are given below. My method was to analyse two specimens in the above manner before the treatment began and then to make a second series of analyses about 10 or 14 days afterwards. In some cases a third series of analyses was made at a later date. In each case the amounts of uric acid given are the mean of two observations. My results are given in the following table.

Case.	Normal diet.				Drinking mineral water.				
	Urine.	Uric acid.			Urine.		Uric acid.		
	Amount in c.c.	Per cent.	Total output per diem.	Days after first experiment.	Amount in c.c.	Increase or decrease per cent.	Per cent.	Total output per diem.	Increase or decrease per cent.

CASE 1.—This was the case of Mr. Russell, which I have referred to above, and which I have inserted for comparison with other cases.

CASE 2.—This patient suffered from pain in the loins, lassitude, and muscular weakness. She passed very little urine, and her appetite was very poor. She had influenza in February, 1899. Under treatment she made considerable improvement, lost the pains, and became more active. Her appetite and general health were very much better. There was at first an increase and then, after a month's treatment, a decrease in the amount of urine passed.

CASE 3.—A man, aged 38 years, had been suffering from rheumatism and gout for nine years. He complained of pain in the loins and between the scapulæ, and also had some stiffness of the joints. He was accustomed to considerable outdoor exercise. After a few days' treatment the uric acid excreted was more than double in amount and the pain was considerably less. After two months' treatment the pain had quite disappeared although the uric acid had diminished from its original amount.

CASE 4.—This patient, a woman, aged 50 years, had suffered from gout and rheumatism for some years. There were signs of osteo-arthritis of both knees and symptoms of chronic gastric catarrh. After a few days' treatment there was an increase of 19 per cent. in the uric acid excreted, and later there was improvement in the condition of the knees.

CASE 5.—A woman had complained of pain in the lumbar region for two years, accompanied by an excessive deposit of uric acid. She had also had symptoms of renal colic. After drinking the mineral water for a fortnight there was an increased output in the urine of 102 per cent., and in the uric acid of 165 per cent. This was accompanied by a diminution of the pain and a general improvement in the patient's health.

CASE 6.—This patient, a female, had suffered for four years from an obscure urinary trouble. She occasionally passed very offensive urine, which occurred generally after overwork and after walking. She then passed much mucus and pus. She had consulted several specialists, but none would give a definite opinion as to the nature of her case. When she came under my care she was in a very weak condition, but her urine was normal. After three weeks' treatment she was much stronger, but the uric acid, which at first increased slightly, afterwards diminished considerably.

CASE 7.—This patient, a man aged 57 years, had suffered from gravel for some years, accompanied by lumbar pain. He occasionally passed fine "sand" in his urine, but had not done so for two months. A year ago there was a slight amount of albuminuria. On examining the abdomen there was some pain over the right kidney. After a few days' treatment I found that he was passing less than half the amount of uric acid, and at the same time he felt much stronger and the pain in the loins was considerably diminished. This improvement continued, and at the same time there was a relative increase in the amount of uric acid.

It will be noted that of the above seven cases, four of them (Case 1, Case 2, Case 3, and Case 5) showed not only a decided relief of the symptoms, but a considerable increase in the output of uric acid. In Case 7, while the symptoms were relieved the uric acid diminished, and the same may be said to a certain extent of Case 6. It will be observed that in all the cases where a later examination was made the uric acid diminished in quantity. Probably the excess accumulated in the system had by that time been removed by the action of the water. In all the cases there was an increase in the flow of urine. That this is not solely due to the increased amount of fluid consumed, but is due partly to the action of the mineral water, was shown in the former article by Mr. Edward Russell and myself, mentioned above.

These results are, on the whole, most encouraging, and they show that in the Llangammarch mineral water we have a powerful agent for the elimination of uric acid. This water is therefore indicated in cases of rheumatism, gout, osteo-arthritis, and in all forms of the uric acid diathesis. In addition, patients who drink the water at the spring have many opportunities for physical exercise in a mountainous district like Llangammarch, thus forming a valuable adjunct to treatment.

Llangammarch Wells, Breconshire.

BRENTRY HOME FOR INEBRIATES.—At a meeting of the Bath Town Council held on June 12th it was decided to enter into an arrangement with the authorities of the Brentry Home for Inebriates, near Bristol, by which for the payment of £1000 seven beds in that institution would be available for 25 years.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum allorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

ST. GEORGE'S HOSPITAL.

A CASE OF HERMAPHRODITISM.

(Under the care of Mr. G. R. TURNER.)

THE frequency of cases of true hermaphroditism is probably not great, but the statistics of the French military revising councils show[1] that a cleft of the scrotum causing an appearance of two labia is met with in about 5 per 1000 of all those rejected. The increase of the intertubular tissue of the testis (noticed in the following case) is mentioned in several of the cases in which the testis of an hermaphrodite has been examined microscopically after having been removed. We refer our readers to an annotation entitled "Marriage between Persons of the Same Sex" which appeared in THE LANCET of June 23rd, p. 1814, and which illustrates the extreme difficulty of diagnosis of sex in some of these cases.

A "girl," aged 14 years, had been "ruptured" ever since birth. She had worn a truss until she was 12 years of age, but since then nothing in the way of a support. She had been in early life under the care of a surgeon to a truss society who had wished to operate. She is the third of a family of six who are all well developed. She had never menstruated. On admission to St. George's Hospital there was a moveable oval irreducible swelling in the left inguinal region which was taken to be a prolapsed ovary. This was removed and proved to be a testis lying over the external abdominal ring. The cord was ligatured and the ring was closed by suture. The operation wound healed by first intention. The naked-eye appearance of the organ removed was that of a well-developed testis, the epididymis of which contained three little cysts. A microscopical examination was made by Dr. H. D. Rolleston and showed that there was no ovarian tissue; there were seminal tubules like those of the testis. In addition there were masses of interstitial cells like those seen in the testis of some of the lower animals.

Gas and ether were subsequently administered to allow of a thorough examination of the individual by Dr. W. R. Dakin and Mr. G. R. Turner. The mammary glands were both well developed for the patient's age. The pubic hair was scanty but the external parts were those of a well-developed female, the labia majora, minora, clitoris, and urethral orifice being normal. The latter was slightly caruncular. The vagina admitted the index finger half way up to the second knuckle. The width of the vagina was normal; it terminated in a cul-de-sac. No cervix uteri could be felt. A very small transverse cord, like a Fallopian tube or vas deferens, could be felt per vaginam. Nothing could be felt in the labia. On bimanual examination a transverse cord could be felt to slip away. This cord was situated one inch behind the pubes. Per rectum the whole pelvis could be explored. There was nothing found—nothing to represent either the uterus or prostate gland. The following were the pelvic measurements: inter-spinous, 8¾ inches; inter-cristal, 9⅝ inches; and external conjugate, 6⅝ inches.

Remarks by Mr. TURNER.—This case would appear to be one of true hermaphroditism in which the external organs of generation are like those of the normal female, the vagina ending in a cul-de-sac with no trace of uterus or ovaries. The inguinal testicle (now in the museum of St. George's Hospital) had all the naked-eye appearance of the normal except that the epididymis was the seat of cystic degeneration. Microscopically, too, the structure was testicular. A somewhat similar case is recorded by Dr. Chambers in the Transactions of the Obstetrical Society of

[1] Lagneau: Le Bulletin Médicale, April, 1895.

London, vol. xxi., page 256. In that case, too, the orifice of the meatus urinarius was irregular and granular; the vagina was an inch long and there was no trace of hymen, uterus, or ovaries. There were present two testicles the glandular structure of which had never undergone its normal development. Leopold records a similar case and Hauf made a post-mortem examination on one in 1873. In Shattock's case of spurious hermaphroditism with cleft scrotum and extreme hypospadias [2] both testes were removed in the course of a radical cure for double inguinal hernia. It is interesting to note that in these testes, as in the one removed from my patient, there was "a highly pronounced group of interstitial cells in the stroma." I have been unable to discover any marked inclination to either of the sexes in my patient. "She" has been brought up as a girl and acts as nurse to her younger relatives.

NEWCASTLE-ON-TYNE ROYAL INFIRMARY.

A CASE OF REMOVAL OF A GALL-STONE FROM THE COMMON BILE DUCT BY THE DUODENAL INCISION.

(Under the care of Mr. FREDERICK PAGE.)

IN the following case a gall-stone impacted in the common bile-duct was removed by an incision through the duodenal wall. This operation has been called duodeno-choledochotomy and was first performed by McBurney,[1] then by Kocher,[2] and for the third time by Mayo Robson.[3] It is a very useful method in some cases, as the stone is frequently fixed in that portion of the common duct which lies behind the duodenum. It has now been performed in about 15 cases with three deaths, a mortality of 20 per cent.

The patient was a woman, aged 59 years, who was admitted into the Newcastle-on-Tyne Royal Infirmary under the care of Mr. F. Page. She had been subject for the past two and a half years to sudden attacks of severe pain in the region of the gall-bladder extending down to the umbilicus and lasting several hours; when very severe it extended through to the back. The attacks were always accompanied by vomiting and shivering, the latter sometimes coming on before the pain. She was troubled in this way about once a fortnight. Three months previously she became jaundiced after an attack of colic; the discolouration had continued more or less

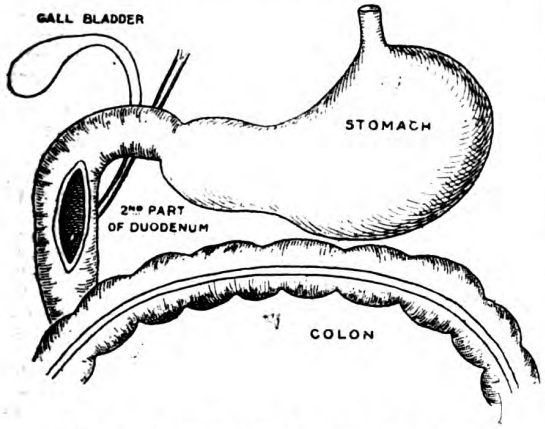

Diagram showing position of incision in duodenum.

until admission. Her family and previous history did not relate anything of importance. She was stout but feeble. The skin and conjunctiva were slightly jaundiced. The urine contained bile. The fæces were clay-coloured and she suffered from constipation. The gall-bladder could not be felt on abdominal palpation. During the seven weeks she was in hospital before operation she had several attacks of biliary colic.

[2] Brit. Med. Jour., vol. i., 1897, p. 460. Annals of Surgery, Oct. 18th, 1895.
[2] Correspondenzblatt für Schweitzer Aerzte, 1895, No. 7.
[3] Gall-bladder and Bile-ducts, second edition, p. 271.

On Oct. 14th chloroform was administered and the operation performed as follows. 1. A vertical incision was made over the situation of the gall-bladder. 2. The stone was felt to the right side of the head of the pancreas, but as very extensive adhesions prevented the common duct from being exposed from the outer side the anterior wall of the second part of the duodenum was incised in the position shown in the diagram, the opening of the common bile duct into the duodenum was incised upwards, and a large gall-stone was removed. The incision into the opening of the common duct was not sutured. 3. The incision through the anterior wall of the duodenum was closed as follows. A continuous catgut suture passing through the three coats of the bowel was first inserted, then the line of suture was covered in by a continuous suture of fine silk passing through the peritoneal coat alone; one or two Lembert's sutures were put in at the ends of the incision. 4. The abdominal wound, which had been enlarged parallel to the right costal margin, was then closed with three tiers of sutures. No drainage was employed. After the operation the patient was troubled with bronchitis but eventually completely recovered.

Remarks by Dr. JOHN CLAY, *surgical registrar*.—In the above case I had the good fortune to assist Mr. Page. It is an example of the simple and rapid method of suture employed by that surgeon. For the notes of the case I am indebted to the house surgeon, Dr. L. F. Hemmans.

Medical Societies.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens.—Nomenclature of Transverse Presentations and of Version.—Set of the Pelvis in the Body.

A MEETING of this society was held on June 13th, Dr. R. MILNE MURRAY, the President, being in the chair.

Dr. N. T. BREWIS showed (1) a Uterus removed by Hysterectomy (sub-peritoneal) after Cæsarean Section at Term; (2) a Gravid Uterus at the fifth month, removed by Panhysterectomy for Cancer of the Cervix; (3) a Uterus removed by Vaginal Hysterectomy for Cancer of the Cervix and Body; and (4) a Pyosalpinx removed by Vaginal Section.

Dr. F. W. N. HAULTAIN showed (1) a Ruptured Extra-uterine Gestation (after the operation a decidua was expelled from the uterus followed by very severe post-decidual hæmorrhage); (2) micro-photographs and microscopical preparation of a Fibro-adenoma of the Vagina; (3) a Cyst from the canal of Nuck; and (4) an Ovarian Cyst which was associated with 920 ounces of ascitic fluid.

Dr. J. W. BALLANTYNE showed photographs of Iniencephaly, Sympodia, Knotted Cord, &c.

Dr. J. HAIG FERGUSON showed a Dermoid Ovarian Tumour removed from a patient four months pregnant.

Dr. D. BERRY HART read a paper on The Nomenclature of Transverse Presentations and of Version, with Remarks on the Choice of the Leg seized. The best nomenclature of the position in transverse presentations was that which divided them into "dorso-anterior" and "dorso-posterior" and each of these again into "left acromio-iliac" and "right acromio-iliac," according as the acromion was to the left side or to the right side. It was better to name the positions from the acromion as it was often the presenting part. This plan was more exact than that which named them after the head, as "right cephalo-iliac" or "left cephalo-iliac." Little could be said in favour of the use of the scapula as the indicating part, as "left scapulo-anterior;" the acromion was a more precise point. The terms "right" and "left" referred to the mother and not to the fœtus. The nomenclature of the varieties of version was at present very confusing. The terms applied to version were descriptive either of the method by which the version was performed or of its aim. In "podalic" or "cephalic" version the aim was to substitute the lower limb or the head for the presenting part. The terms "bipolar version" and "external version" applied to method. Dr. Hart defined three great varieties of version: (1) combined external version (cephalic) which was now seldom used in practice and was practically performed by external manipulation, its aim being to get the head to present; (2) Simpson's combined version

(podalic) which was carried out by one hand placed externally on the abdomen and the other hand passed deeply into the uterus, its aim being "podalic," as it was to bring the lower limb to present; and (3) Braxton Hicks's bipolar version (podalic) which was performed with one hand external and the other internal but not deep (the hand should not be passed beyond the presenting part), the aim of which also was podalic. The second and third methods might for shortness be called "Simpson's podalic" version and "Hicks's podalic" version. In the choice of the leg seized Simpson advocated the further knee, and Galabin advocated the near foot as a rule. Simpson's original case was a dorso-posterior one and Galabin's a dorso-anterior one. In a simple case they could turn easily whichever leg was taken and the leg seized would come to the front in the end. In difficult cases, with the liquor amnii partly drained off, it was of importance to seize the knee which gave the safer operation. Nagel had given by far the most complete discussion of the subject. He did not consider the question of the leg to be seized merely from the point of view of the accomplishment of the version, but indicated that the leg, the half breech of which would pass sooner to the symphysis, should be seized, thus taking the standpoint of the older observers, Baudelocque and Hohl, and of his own master, Gusserow. Dr. Hart summed up as follows:—"Seize the knee or leg which maintains the dorso-anterior position or converts the dorso-posterior into a dorso-anterior—that is, take the further limb in dorso-posterior cases, the nearer in dorso-anterior cases. When, however, in dorso-anterior cases the breech is in the fundus traction on the nearer leg may convert it into a dorso-posterior, and when the breech is near the os in dorso-posterior position traction on the further leg may not alter the posterior position of the back after version, owing, again, to the want of the necessary obliquity in the pull."—Professor A. R. SIMPSON, the PRESIDENT, Dr. A. H. F. BARBOUR, and Dr. S. MCVIE discussed the paper.

Dr. A. H. FREELAND BARBOUR read a paper on the Set of the Pelvis in the Body (Inclination of the Brim apart from Posture) and its Obstetrical Significance. The inclination of the brim, instead of being described in reference to the horizontal plane, might be described with the subject lying on the back, in relation to a perpendicular let fall from the upper margin of the symphysis on a line passing through the promontory of the sacrum in the direction of the long axis of the abdomen. The advantage of this method was that instead of taking a plane outside of the body, which had no obstetrical significance and to which the relation of the pelvis changed with every posture, a fixed line within the body was taken. The angle of divergence of the plane of the brim (i.e., the plane passing through the conjugate of the brim) from this perpendicular was necessarily the same as the angle of divergence of the axis of the brim from the long axis of the abdomen. The smaller this angle—i.e., the more nearly the plane of the brim approached in direction with this line—the more did the pelvic inlet come into line with the long axis of the abdomen. The range of divergence in pelves which were obstetrically normal was considerable, varying from 40 degrees to 60 degrees. While a mean might be taken of 55 degrees, the variability of pelves from this, within certain limits, was a more important fact than the constancy of this angle which the mention of a figure was apt to convey. Though they were not in a position to gather up from clinical observation the results of this anatomical fact, owing to the difficulties of determining the size of this angle in the living subject, it was evident that its variability must exert a distinct influence on the engagement of the head and the driving power of the uterus in multiparæ. Dr. Barbour then discussed the work of Naegele, Weber, Meyer, and Prowchownik on the inclination of the brim clinically and the effect of posture on it. He also specially referred to the recent work of Dr. Sandstein who measured the height of the promontory above the symphysis in 28 cadavers, noting also the length of the conjugate. The true conjugate was found to range from four inches to 5·8 inches; and the height of the promontory from 3·7 inches to 5·4 inches above the symphysis. It was found that an increase in the length of the conjugate did not imply a proportionate rise in the level of the promontory, the cause of the variation in its level being the variability of the set of the brim which had a range of nearly 20 degrees.—The PRESIDENT and Professor A. R. SIMPSON made remarks on the paper.

CHELSEA CLINICAL SOCIETY.—At the annual meeting of this society, held on May 15th, Mr. J. Foster Palmer, the President, being in the chair, the following gentlemen were elected office-bearers for the session 1900–1901:—President: Dr. William Ewart. Vice-Presidents: Dr. C. C. Gibbes, Dr. C. J. Harrison, Mr. C. A. Morris, and Mr. A. F. Penny. Council: Dr. J. Barry Ball, Dr. J. Blumfeld, Dr. T. Vincent Dickinson, Mr. J. J. Marsh, Mr. J. W. E. Mortimer, and Mr. W. H. C. Staveley. Treasurer: Dr. A. Barry Blacker. Secretaries: Dr. Austin E. Cooper and Mr. R. L. Norman.—Mr. Foster Palmer, having expressed his hearty thanks to the vice-presidents and other members of the council as well as to the members of the society generally for their valuable coöperation and support during the last two years, proceeded to give a short valedictory address on some of the enemies—in a metaphysical sense—of the society, past, present, and future. These, which he characterised as demons, were Ignorance, Idleness, Superstition, and Fads founded on Folly. In accounting for the persistent vitality of some of these Fads he dwelt on the advantage Ignorance often possessed in being absolutely uncontrolled by the inconvenient knowledge of scientific facts and thus being able to give free scope to the powers of rhetoric and imagination. At the same time he thought the issues were still further obscured by the tendency to clothe their statements too much in technical or scientific language, and he advocated the cultivation of a simpler Anglo-Saxon diction without going quite so far as to adopt the powerful slang phraseology of John Hunter. The particular Fads referred to were as follows. 1. Anti-vaccination.—The undoubted facts of the remarkable diminution of small-pox and the rare occurrence of insusceptibility even now among the unvaccinated were alluded to and shown to be inadequately met by the prevalent objections that general sanitation had been the cause of the diminution and that the statistics had been falsified or wrongly interpreted. The case for vaccination did not rest wholly upon statistics. 2. Anti-vivisection.—The difficulty of tracing, and even of understanding, the progress of scientific research to those untrained in science was as great as that of grasping legal technicalities was to those untrained in law. On this subject, therefore, imagination and rhetoric had both run wild and it readily lent itself to both. The constant persistence of the Fad was partly due no doubt to the prevalent hatred of science and its professors in England (and in England alone), but also to some extent to the hyper-technical and scientific diction already referred to. Otherwise, surely Professor Huxley's argument, stated many years ago in the *Nineteenth Century*, would have convinced all who believed in the utility of experiments. If, he said, the alternative was actually put, and they had to choose between the sacrifice of a dog and the sacrifice of a man, which was it to be? There was no choice. To save the dog in such a case would mean murder, and all who encouraged the act by word or deed would be accomplices. This was how the experimenters viewed the case, and, sad as the alternative was, they had no choice. Most of the anti-vivisectionists, however, pinned their faith absolutely on the uselessness of experiments. Was there no way of convincing anti-vivisectionists of what was so patent to them? Most of them had seen life saved by the injection of strychnine, and all the applications of strychnine, as Sir T. Lauder Brunton says, were the direct consequences of physiological experiment. 3. Teetotalism.—Without definitely including this among the Fads Mr. Foster Palmer here ventured to take exception to some of the experiments quoted by Mr. Horsley on the ground that alcohol taken otherwise than as part of a meal (i.e., a good dinner) was taken in an abnormal and unnatural manner. It required neither argument nor experiment to condemn nips of alcohol taken on an empty stomach. Nor was rapidity of thought necessarily an absolute test of mental and physical health, or the occasional slowing of thought necessarily an evil as seemed to be assumed. The net result appeared to be that alcohol was not a stimulant at all, but was in reality a depressant causing a delusive feeling of stimulation. It was merely a change of names. "That which we call a glass of port, by any other name, &c." The actual physiological and therapeutical value of alcohol remained unaffected. Mr. Foster Palmer concluded by expressing a hearty wish for the future progress of the Chelsea Clinical Society.

WIGAN MEDICAL SOCIETY.—An ordinary meeting of this society was held on June 21st, Mr. R. H. Cowan, the

President, being in the chair, and there was a good attendance of members.—The President gave his presidential address on Some Experiences of Colliery Surgery. The address was an excellent one and was very interesting to the members.—Mr. Hugh E. Jones showed some naked-eye specimens illustrating the Anatomy and Pathology of the Ear, and supplemented the demonstration with some remarks on the Surgery of Middle-ear Disease.—A cordial vote of thanks was passed to the President for his address and to Mr. Jones for his interesting demonstration.—The President and Mr. Jones replied.

Reviews and Notices of Books.

A Manual of Medicine. Edited by W. H. ALLCHIN, M.D., F.R.C.P. Lond., F.R.S. Edin., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital, &c. Vol. I.: General Diseases. London: Macmillan and Co., Limited. 1900. Pp. 442. Price 7*s.* 6*d.*

THIS work is the latest addition to those publications which are not written by one author but issued under the editorship of a recognised authority, the various subjects being considered by different writers. The forms of disease are viewed more especially from the point of view of their clinical manifestations and treatment. The subjects of etiology and morbid anatomy are briefly summarised, but for further knowledge of these aspects of disease the reader is referred to other works. The aim of the editor has been to present such a picture of the several maladies as will conform to the appearances detected at the bedside and enable the observer rationally to administer such treatment as our art affords.

The present volume deals with "Diseases Excited by Atmospheric Influences" and "The Infections." The article on the first-named is written by the editor, Dr. W. H. Allchin, and includes the effect on the human body of heat and cold and also the phenomena produced by exposure to increased or decreased atmospheric pressure. A reference is also made to "lightning stroke." The chapter is a brief one but contains a large amount of useful information. It will be especially appreciated by those who desire to obtain a clinical knowledge of the conditions alluded to without having to glance through a long article containing a commentary on the various theories which from time to time have been brought forward to account for the phenomena encountered under such varying atmospheric influences. Professor G. Sims Woodhead contributes a most able paper on "The Infections." He gives a brief review of the general characters of the pathogenic micro-organisms and the toxic products of bacteria. Natural and acquired immunity are likewise discussed and also the question of "predisposition" to certain disease of bacterial origin. Details as to the general course and characters of the infective disease follow, especial reference being made to "mixed infections" which are by no means uncommon.

A series of articles then follows on the various "fevers." Many of these are of unusual interest, such as those on Tropical Diseases. Mr. James Cantlie writes on Cholera, Plague, Leprosy, Dengue, Beri-beri, Epidemic Dropsy, Oriental Sore, Dysentery, Malaria, Hæmoglobinuric Fever, and Kala-Azar, whilst an article on Mediterranean Fever is from the pen of the late Captain M. L. Hughes, R.A.M.C. Major W. G. Macpherson, R.A.M.C., contributes the article on Yellow Fever and Dr. Colcott Fox writes on Verruga and Frambœsia. This volume, therefore, should be particularly valuable to those practising in the climates where the above-mentioned fevers are met with.

Out of 45 articles it would be difficult to select any one for especial praise. All the authors seem to have carried out the intention of the editor and to have written their contributions from a clinical rather than from a pathological oint of view.

Dr. J. Rose Bradford is responsible for the articles on Mycoses and Rabies. In reference to the latter he urges that the Pasteur treatment should be applied as soon as possible if there are good grounds for suspecting the animal which attacked the patient to be rabid, and that the treatment should not be delayed until the diagnosis has been confirmed by the inoculation test, as thereby three weeks may be lost and the disease declare itself before protective measures can be carried out. Dr. F. F. Caiger contributes interesting articles on Diphtheria, Measles, Rötheln, Scarlet Fever, and Varicella.

One of the best contributions in this volume is that by Dr. W. Cayley on Typhoid Fever, and particularly interesting are his remarks on the "Complications and Sequelæ." Hæmorrhage and perforation naturally occupy the foremost place, but stress is also laid on the respiratory and nervous complications which may occur. With regard to the latter, peripheral neuritis and "typhoid spine" are mentioned as considerably prolonging the discomfort and sufferings of the patient. Dr. Cayley speaks highly of the "bath treatment' of typhoid fever, or when bathing cannot be employed of sponging. Details are given of both these methods which practitioners should have no difficulty in following.

Another instructive article is that on Acute and Sub-acute Rheumatism, by Dr. D. B. Lees. Attention will no doubt be directed to the section on Pathology. The remarks here found admirably sum up the views rapidly becoming accepted, that acute rheumatism is not essentially a joint disease. Dr. Lees says: "The true nature and origin of this disease are still unknown; but the facts already stated make it certain that no neurotic theory and no theory of perverted metabolism can fully account for the phenomena; these strongly suggest a microbic infection. The greater frequency and greater virulence of rheumatism in childhood remind the physician of the infectious fevers, and the occasional occurrence of sore-throat and of a characteristic eruption, with the pyrexia, are other points of resemblance. ..... No microbe has yet been proved to be the cause of rheumatism, but the same is true of such undoubtedly microbic diseases as measles, scarlet fever, whooping cough, and syphilis." Acute rheumatism and lobar pneumonia seem now to have taken their permanent places amongst "the infections."

No better author could have been found for the contributions on Variola and Vaccinia than Dr. S. M. Copeman and both these articles will well repay perusal.

There are numerous other well-known authorities who contribute to this volume, such as Dr. J. W. Washbourn (Erysipelas, Infective Endocarditis, Relapsing Fever, and Weil's Disease) and Dr. W. Hale White ("Fever"), but we have said sufficient to indicate the high level of excellence apparent in this first volume of a manual for which we predict success.

The Diseases of Women: a Handbook for Students and Practitioners. By J. BLAND-SUTTON, F.R.C.S. Eng., and ARTHUR E. GILES, M.D., B.Sc. Lond., F.R.C.S. Edin. Second edition. Crown 8vo. With 115 Illustrations (mostly original) in the text. London: Rebman, Limited. 1900. Pp. 473. Price 11*s.* net.

THE appearance of a second edition of this text-book has been taken advantage of by the authors to carry out a careful revision. They have succeeded in doing this without unduly increasing the size of the volume. Only 37 new pages have been added, while the number of illustrations remains the same. Amongst the numerous additions that have been made the chapter upon Vaginal Secretions and Vaginal Infections has been brought thoroughly up to date and now presents a very clear and succinct account of the important rôle played by the vaginal bacillus. The authors are inclined to overrate the importance of some of the subjects which they describe and in consequence the book is

somewhat ill-balanced. For example, 33 pages are devoted to a consideration of myomata of the uterus and only eight to that of carcinoma of the body and cervix of the uterus. The practice of describing epithelioma apart from carcinoma is not one that conduces to clearness in teaching students. Squamous carcinoma is quite correct and certainly a less misleading term. There are some curious omissions. Nowhere do we find any account of the method of introducing a Hodge's pessary. No mention is made of conservative operations under the surgical treatment of diseases of the Fallopian tubes and J. Taylor's classification of intra-ligamentary gestation is not given. Abdominal drainage after cœliotomy is described, but not vaginal, and nothing is said as to the great value of intermittent uterine contractions in the differential diagnosis of hydramnion. As might be expected, one of the best sections is that upon tubal pregnancy. It is interesting to note that of the authors' large series of cases the proportion of tubal abortion to tubal rupture has not been more than one to four. The important statement that no decidua forms in the tube in cases of tubal gestation is based upon the careful microscopical examination of 25 early gravid tubes. In the surgical treatment of myomata the operation of oöphorectomy is regarded as obsolete, to be replaced by conservative hysterectomy, one or other ovary being left. The opinion which we expressed in our review of the first edition of the book still holds good—viz., that the authors are inclined to neglect the medical treatment of gynæcological cases and that a student in reading the somewhat sketchy account of some of the most important major operations might be led to look upon them as easy and to recommend them without a due regard to their difficulties and dangers. In these days when operative gynæcology is so much to the fore we cannot help regarding this as somewhat of a defect in an otherwise excellent book. While we may not agree with all which the authors teach, yet we must admit that their practice is not wanting in boldness of conception or their views in lucidity of expression. Several of the new illustrations are of great interest, notably No. 17 and No. 18, a case of hematocolpos and hæmatometra in the newborn child compressing the urethra and ureter, and No. 87, a cystic ovary containing a calcified corpus fibrosum. By a diminution in the size of the pages the book is rendered easier to hold and the appearance of the print is improved. The index has been considerably enlarged and we must congratulate both the authors and the publishers upon the care that has been expended in the preparation of this new edition.

A Treatise on Nasal Suppuration; or, Suppurative Diseases of the Nose and its Accessory Sinuses. By Dr. LUDWIG GRÜNWALD of Munich. Translated from the Second German Edition by WILLIAM LAMB, M.D., M.C. Edin., M.R.C.P. Lond. With eight Illustrations in the Text, Two Plates, and One Table. London: Baillière, Tindall, and Cox. 1900.

THIS is a work of 316 pages with a copious bibliographical list of references and an index. The first part is general and deals with symptomatology and secondary diseases. The subjective disturbances of smell and sight together with mental processes are fully discussed, with such associated troubles as polypi, intracranial suppuration, and septicæmia. The methods of examination and prognosis are fully described.

The second part deals with special sources of suppuration, and here, as would be expected, the antrum and ethmoidal cells and the frontal sinus and sphenoidal cavity receive due attention.

A careful perusal of this book shows the labour bestowed upon it and impresses the reader with the fact that it is largely the outcome of the best sort of work—personal observation and research. Full lists are given from the author's actual experience of various conditions and symptoms which are of the highest practical importance. He has also endeavoured to combine pathological changes with clinical research and to explain their correlation, a matter of no ordinary difficulty, especially in this region of the body.

Speaking generally, we have read this book with a sense of disappointment. This is not due to the work itself, which is one of excellence, but to the fact that the author, though a man of unrivalled experience in this particular subject, has to confess to the almost insuperable difficulties which attend the diagnosis, especially the differential diagnosis, of sinus suppurations, and the too often tedious and negative results of treatment. We have often experienced these difficulties, and the clouds of doubt and difficulty which surround them are not lifted from our path by Dr. Grünwald's book. This wise and skilful observer does not hesitate to tell us that he has experienced cases of chronic antral empyemata which are incurable by all ordinary methods—a striking contrast to the "universal cures" claimed by some observers in this and other countries. In discussing the diagnosis of latent frontal empyemata a close reader will see that in the author's mind certain doubts arise as to the value of catheterisation and the position of drops of pus in the nasal chambers, and we are driven to the conclusion that a small exploratory opening is often needful to settle a vexed and difficult question.

The author thinks highly of the method of "damming back" certain areas of the nose in making differential diagnosis, but this again must in practice be difficult and very likely to lead a too confident observer totally astray.

The value of this book consists in its obvious honesty and in the wealth of clinical observation submitted. A close study of it will show how neglected the subject of nasal suppurations has been in the past and what a rich field for diagnostic research and improved treatment lies open in the future.

LIBRARY TABLE.

Burdett's Hospitals and Charities, 1900. By Sir HENRY BURDETT, K.C.B. London: The Scientific Press, Ltd. Pp. 958. Price 5*s*.—The eleventh issue of this useful book of reference is in no way behind any of its predecessors. To anyone who wishes to know about hospitals, as to their management, income, or the medical staffs and their hours of attendance, we commend the work as a mine of information. From the introductory chapters we learn that, excluding St. Bartholomew's Hospital, 75 of the London hospitals have invested property amounting to upwards of £4,000,000. Of these 75, 35 have invested property amounting to less than three years' ordinary expenditure, 21 have funds invested amounting to from three to five years' ordinary expenditure, and 18 have invested funds amounting to more than five years' ordinary expenditure.

My Diocese during the War. By the Bishop of NATAL. London: George Bell and Sons. Pp. 266. Price 6*s*.—This is in no sense to be taken as a deliberately thought-of comment upon the events of which it treats, for the book is merely a transcript of portions of Dr. Baynes's daily diary. But as notes of the observation of an intelligent and thoughtful civilian, of one who, owing to his official position, was affected to a far wider degree, and in even more distressful ways, than the ordinary civilian, the book is well worth reading. The notes go down to the end of April. Among the illustrations are some reproductions of drawings by the Bishop and also some photographs by Mr. Clinton Dent, including the views of the Boer trenches at Magersfontein which we had the privilege of publishing in our issue of June 2nd.

JOURNALS.

Records from General Practice. By J. KINGSTON BARTON, M.R.C.P. Lond., M.R.C.S. Eng. London: John Bale, Sons, and Danielsson. June, 1900. Pp. 84. Price 2*s.* 6*d.*—Few general practitioners can find time to take written notes of, and observations upon, their patients' cases, and there is no doubt that much clinical information is lost thereby. Mr. J. Kingston Barton has had the perseverance to keep a record of a large number of cases during the last 20 years and now has formed the very praiseworthy intention to publish some of them. The first instalment appears in the form of a periodical and others will be published "from time to time." The first number contains the report of several interesting cases, notably a summary of 50 cases of acute abdominal affection, including 32 cases of appendicitis and seven of gastric ulcer. There are also some instructive observations on conditions of the teeth—Erosion of the Teeth in Children, the Ratio of Occurrence of Deficient Enamel, and Early Decay of the Teeth. The last article in the book is an appropriate one for this time of the year—viz., Holidays, with Notes on the Life-History of the Salmon. Mr. Barton may be congratulated on his publication and we wish it every success.

Edinburgh Medical Journal.—The June number opens with a long paper by Dr. Louis Cobbett entitled, "Has Antitoxine reduced the Death-rate from Diphtheria in our Large Towns?" A consideration of the statistics supplied by nine large towns in Great Britain for varying periods of years shows that a remarkable fall, both in the diphtheria death-rate and case mortality, has occurred since 1894. Several causes may have contributed to this change, but there appears to be every reason for believing that the most efficient of all was the introduction of diphtheria antitoxin. Dr. Cobbett says that the diphtheria bacillus may remain in a dangerous state for a very long time in the mouths of those who have recovered, so that convalescents can be declared free from infection only after the disappearance of the bacillus has been ascertained, and not at the end of any arbitrarily selected period such as three weeks. Altogether there are five original articles.

Scottish Medical and Surgical Journal.—In the June number Professor A. R. Simpson of Edinburgh writes on the application of the steam of boiling water to the endometrium. This may be done in two ways, either by leading the steam through a fenestrated catheter into the uterine cavity (atmokausis) or by passing into the uterus a non-fenestrated catheter heated by steam which is not allowed to escape into the uterus (zestokausis). In the Edinburgh Royal Infirmary Professor Simpson has used the treatment in 14 cases of endometritis with menorrhagia or metrorrhagia. It was always carried out under chloroform narcosis and was usually continued for 45 seconds. Of the 14 cases 11 were cured and three were improved. In a long paper, entitled "Heredity in Disease," Dr. G. Archdall Reid speculates on some of the far-reaching effects of various maladies, such as the extinction of certain uncivilised populations through the spread of tuberculosis among them after the advent of superior races.

Dublin Journal of Medical Science.—The original articles in the June number are on Toxins and Antitoxins, by Dr. A. C. O'Sullivan; on Commercial Pepsin, by Sir Charles A. Cameron; and on the Dublin Method of Effecting the Delivery of the Placenta, by Dr. Henry Jellett.

Mercy and Truth.—The June number was issued before the recent outbreak of hostilities in China. It contains articles on the Work of Medical Missions in Persia, by Dr. D. W. Carr, of Julfa; on Overcoming Obstacles in China, by Mr. L. G. Hill, of Pakhoi; and on Opening a Way for the Gospel, by Dr. Mabel Poulter, of Hok-Chiang, South China.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE FRIENDLY SOCIETY.

THIS society, which was founded in 1884 with a somewhat multifarious programme, has now become, as the result of experience, a sickness insurance society exclusively so far as the transaction of new business is concerned. In making this change the directors have, we think, been well advised, for the accumulation of funds to provide deferred benefits is an operation which cannot be carried out economically on a small scale, and this society, therefore, has never been in a position to compete favourably with the better sort of life assurance offices in this department of its work. The annuity department has accordingly been closed and is now being conducted with a view simply to the working out of subsisting contracts. The business of life assurance is carried on by means of a sort of agency arrangement, by which proposals reaching the society are handed on to a particular office, but the connexion between the society and the insurance office is in no sense organic and, indeed, not, as we understand, particularly close. We think that a connexion of that sort cannot be too slight, for it is a serious responsibility to advise a man who is proposing to effect an insurance on his life as to the choice of an office, and the method upon which the society proceeds does not seem to us to involve sufficient discrimination. It is certainly not desirable that the entire insurance business of the profession should be turned into one channel, nor is the office which most readily concedes a rebate from its premium rates likely to be the one which will make the best return to the policy-holder for the premium actually received. It cannot be too often or too impressively pointed out that the secret of good finance in life assurance is the cutting down of all expenditure other than that on benefits to members to the lowest possible percentage of the annual outgo. A rebate from the annual premium may indeed be classed as a benefit when it is made to the policy-holder himself, but it may be doubted whether in fact any benefit in that form is the monetary equivalent of the savings effected by those offices which, eschewing all costly forms of advertisement, are conducted with a view to the benefit alone of the insured members.

But it is no part of our purpose to criticise the choice which the society has made of a patron among the life assurance companies. It is with its own proper work of sickness insurance that we are more concerned, and here we have the satisfaction of saying that the seventeenth report recently issued to the members is entirely satisfactory. The members paid in premiums about £11,300, plus 10 per cent.—say, £12,430—and received in benefit just over £13,000. The difference is made up for the most part of interest upon the investments standing to the credit of this fund; for although these investments were drawn upon to answer the bonus distributed to the members in this "Bonus" year the amount coming from that source was no more than £250. Such a result is in the highest degree creditable to the management of the society and shows that in this department the members obtain their full money's worth in the form of benefit. If to the mere balancing of the account we add the priceless boon of an insurance scheme which carries the invalided practitioner over a period of sickness without any heavy demand upon his savings or other resources we see at once that the aid which this society renders is not to be measured by its mere money worth and that the presentation of a satisfactory balance-sheet, although indispensable, is the least of the claims which the committee are entitled to put forward for the recognition and gratitude of the profession.

The present annual report is accompanied by an actuarial report which does not call for any particular comment.

BRITISH MEDICAL ASSOCIATION, SOUTH-WESTERN BRANCH.—The annual meeting of the South-Western Branch of the British Medical Association was held at Torquay on June 20th. Mr. Paul Q. Karkeek read an interesting paper upon Pre-professional Education of the Medical Student. The secretary (Dr. H. W. Webber) stated that the branch had now a membership of 358. A vote of thanks was awarded to the retiring president, Dr. Mark Jackson of Barnstaple. It was decided that the next annual meeting should be held at Devonport and that Mr. G. Thom should be the president-elect. The dinner was held in the evening under the presidency of Mr. Karkeek.

THE LANCET.

LONDON: SATURDAY, JUNE 30, 1900.

THE crisis in North China, which is causing us such anxiety about the welfare of our countrymen, has also a sad side when considered from a humanitarian point of view. The Chinese, with all their boasted civilisation, have as regards the science and art of surgery and the knowledge and practice of medicine not advanced beyond empiricism. They have kept their healing art in the region of magic with its mythical rites and incantations. No savage tribe or unlettered people practises surgery or medicine in a more primitive fashion or invoke the powers of paganism with more zeal or veneration than do the Chinese. The consequence of this backwardness in medical education must have appalling results at the present moment, when thousands of Chinese are being wounded partly at the hands of their fellow-countrymen and partly by a foreign foe. And while these ignorant fanatics must be punished no medical mind likes to contemplate the idea of neglected surgical injuries. During the Chino-Japanese war the ambulance equipment of the Chinese was rudimentary in the extreme but at the present moment, when undisciplined hordes are being mowed down by Maxims the medical arrangements must be altogether discounted and the condition of the wounded terrible to contemplate.

At Tientsin and Hong-Kong schools of medicine have been established for several years past. At Tientsin LI HUNG CHANG, at the instigation of Dr. IRWIN, inaugurated a medical school some ten years ago and the British Government seconded a medical officer from the British army, Surgeon-Major F. S. HEUSTON, to take up the work of superintending the teaching in the institution. LI HUNG CHANG'S primary idea in establishing the school was to provide medical men trained in Western medicine for service in his army and navy. We use the word "his" army and navy advisedly, for it was only in LI HUNG CHANG'S province of Chihli, of which he was formerly Viceroy, that anything like a modern army and navy existed in China. In 1887 a college of medicine for Chinese was opened in Hong-Kong. The school was initiated and its regulations were drawn up by Mr. JAMES CANTLIE, and Dr. PATRICK MANSON was the first dean. The Viceroy, LI HUNG CHANG, was (and is still) the patron, and in the letter of his acceptance of the position this head and front of Chinese mandarinism, this impersonation of anti-foreign education, wrote that "he hoped that anatomy and chemistry would form a prominent part in the training of the students, for he held these sciences to be the basis of all true medical knowledge." The grasp of knowledge expressed in these words by a man ignorant of science, steeped in Chinese prejudices and old-time mythology, is notable. The Hong-Kong and Tientsin schools are the only attempts in China at systematic teaching of modern medicine and surgery, and the Hong-Kong school especially has been attended with considerable success. The teachers are unpaid; the medical men in the colony have for 14 years now given their services willingly and gratuitously, but as yet no Government aid has been given to support this eminently useful work. Ambulance work was taught in Formosa by Dr. W. W. MYERS, and in Hong-Kong a bearer section was inaugurated, equipped and maintained by Mr. CANTLIE from amongst the students of the College of Medicine. This bearer section was attached to the Hong-Kong Volunteer Artillery, and has done excellent work.

With these exceptions there are no medical schools in China. There are Chinese practitioners in plenty, but their knowledge and practices would afford material for a comic opera rather than for serious consideration. A plaster to mend a fractured leg; a live duck split up and applied to the skin for a poultice; duck's blood smeared on the temples, face, and neck to relieve fever and headache; and "dragon's" blood and deer's horn to cure leprosy are examples of the practice of medicine in China, with which is combined the burning of printed emblems purporting to beseech the Evil One to ward off illness and death. The medical missionaries from Great Britain and the United States of America have done a great deal of excellent hospital work in China; but it is perhaps unfortunate that the medical work has been accompanied in almost every instance by religious proselytising. There seems little reason to doubt the fact that the progress of medicine and, what is still more important, the progress of general education and science and even of civilisation, have been thwarted by the fact that the converts are in most instances tinged with conversion to a new religion. The young Chinese trained in medicine are almost all Christians, and the fact is deterrent to the advance of medical science amongst the Chinese. We believe that were science to be taught to the Chinese in a purely secular way Christianity might follow, but it seems impossible to civilise the Chinese by means of Christianity. The Japanese have become civilised irrespectively of Christianity. Encourage secular Western education and especially medical science in China, send Chinamen thus trained into every centre and town of China, and a leaven will be introduced and a diffusion of knowledge spread through the length and breadth of China which will in the near future bring many good things in its train—among others, we truly believe, a considerable conversion of Chinamen to Christianity.

WEDNESDAY, June 20th, 1900, should be a memorable day in the history of Newcastle-on-Tyne, for on that day the new Infirmary was opened. The men of the north do nothing by halves. When they work they work, and when the vast and varied industries of the neighbourhood cease they play with equal energy. The laying of the foundation-stone of the new Infirmary—one of the many outcomes of the Diamond Jubilee of QUEEN VICTORIA—by the PRINCE OF WALES was an occasion which called forth all their enthusiasm. The huge works of the district were closed, and the resources of the North-Eastern Railway

were strained to bring the population of the counties of Durham and Northumberland into the decorated streets of Newcastle.

The Royal Infirmary of Newcastle has always been a conspicuous institution of the district. For a century and a half it has existed and has been served by physicians and surgeons who have left their mark on the history of the various branches of the healing art, while the members of its present staff of officers have entered thoroughly into the spirit of modern surgery and medicine and fully keep up the reputation of their predecessors. The proof of this lies in the fact that they have neutralised to a great extent the evils inseparably connected with ancient structures, so that the results of the work done were as excellent as when the Infirmary was new. This is a happy omen for the future when the staff will be working in the new building the foundation-stone of which has just been laid in the name of QUEEN VICTORIA by His Royal Highness the PRINCE OF WALES. The ending of an old hospital and the creation of a new one by the employment of all that is best in modern hygiene and medicine are no light undertaking. The promoters of the scheme for rebuilding Newcastle Infirmary have been favoured by the generosity of the citizens of that town, by public respect for the institution, by the high reputation of the staff, and by the harmonious coöperation of the Mayor and Corporation with the committee and staff of the Infirmary. The movement in Newcastle has now received an immense impetus from its Royal associations. The personal popularity of the PRINCE OF WALES is only second to that of Her Majesty the QUEEN. The PRINCE OF WALES has achieved for himself the enviable reputation of being a friend of hospitals—which means the friend of many friendless and truly pitiable people whose sickness is complicated with poverty. We have not always agreed with all that has been done under the name of His Royal Highness for the good of hospitals, but it is impossible not to recognise his great interest in these institutions and his efforts to eliminate all that is objectionable in their administration and to make them wholly beneficent influences. So far it has been chiefly in regard to metropolitan hospitals that the benevolent labours of the PRINCE OF WALES have been exercised, but his Newcastle visit will show that he has an equal interest in provincial hospitals. The PRINCE OF WALES went through the onerous duties of the occasion in a perfect style, his clear, short, pointed speeches being models of public speaking for such purposes. Nothing seemed to be omitted, nobody was forgotten. Even when the programme was defective he filled in the gaps, for he noticed the absence of the name of the Mayoress from the toast list at the luncheon. The munificent donor of £100,000—alas, now dead—and the generous contributions of the working men, amounting to £20,000, were alike remembered. He made it clear, not only by his words but by his whole demeanour, that he was perfectly at home in promoting the erection of a new infirmary. They inadequately judge the PRINCE OF WALES who fail to note the strong elements of benevolence and common-sense which characterise his public actions not less than his public speeches. His influence and his example may be the very saving of our voluntary hospital system, and they have never been more happily or properly used than in his visit to Newcastle.

It is no detraction from all this praise to say that the PRINCE OF WALES made it clear throughout that he was really representing his illustrious—or as he preferred to say his "dear"—mother. The sensible community of Newcastle could well understand the various reasons in this eventful year why the QUEEN could not undertake this work in addition to all the exceptional duties which have devolved upon her. The loyal and affectionate words used repeatedly by the PRINCE OF WALES on this subject went straight to the hearts of those whom he was addressing; and they were as grateful to the QUEEN for nominating the PRINCE as they were to His Royal Highness for coming so gladly and for bringing with him the PRINCESS OF WALES and their daughter, PRINCESS VICTORIA.

THE application made recently in the Queen's Bench Division of the High Court of Justice in the case of Bynoe *v.* the General Medical Council revives a story which attracted some attention a few years ago of a medical practitioner who if he is not a cunning and persistent criminal is one of the most cruelly wronged and unfortunate of men. The subject of the application was Mr. C. A. BYNOE, a medical man practising in London who in 1892 was convicted of forgery at the Old Bailey before Mr. Justice CAVE and sentenced to nine years' penal servitude. The fact of his conviction was in due course brought before the General Medical Council and his name was removed from the Register. During his incarceration continual efforts were made by him and by his relatives on his behalf to establish his innocence, which he had always strenuously asserted. New evidence and arguments were laid before the Home Office, but that department declined to advise either a "free pardon" or an abbreviation of sentence. But now that Mr. BYNOE has served his sentence in full he still maintains his innocence and hopes to establish it. With this view he sought the aid of the High Court that the Court might by its order compel the General Medical Council to hear his application to have his name restored to the Register. Such a proceeding would, of course, involve the re-opening of the question of his guilt, the reviewing of the evidence given at his trial, and the hearing of the new evidence which he is now prepared to adduce in modification or contradiction of testimony which had told against him. This order the Court declined to make, Mr. Justice GRANTHAM saying that to do so would place the General Medical Council in the position of judge and jury in a most complex and difficult case. Mr. Justice CHANNELL said that the Council had a discretion to re-hear the case, but there was no duty upon them to do so, and therefore the Court would not grant a *mandamus*.

That the General Medical Council, had it undertaken or had it been compelled to hold the proposed inquiry, would have had an exceedingly arduous and difficult duty to perform will be gathered from the following by no means exhaustive story of the case. Mr. BYNOE and his mother previously to his conviction kept a boarding-house at 1, Endsleigh-gardens, while he

practised at a surgery in the neighbourhood. At this boarding-house at one time resided a Miss POTTS, a lady of private means and intemperate habits, and a Mr. KIRK, her friend. After both these persons had left the boarding-house letters continued to arrive for Miss POTTS which were not forwarded to her, and some of these contained warrants for the payment of dividends upon stocks and shares owned by her. Certain of the dividend warrants which came in this way to 1, Endsleigh-gardens, and which bore Miss POTTS'S name forged upon them, were undoubtedly cashed by someone. Again, someone, presumably the same unscrupulous person, with considerable ingenuity wrote in Miss POTTS'S name to the companies issuing the warrants and stating that Miss POTTS had lost her certificates asked for duplicates of these documents to be sent to 1, Endsleigh-gardens, and forwarded the required indemnities. On these indemnities appeared the signatures of Miss POTTS and of her friend Mr. KIRK, both forged. The person who obtained the duplicate certificates also sold Miss POTTS'S holding in one of the companies, and to help him to procure an open cheque for the amount this person, a man, took a woman who personated Miss POTTS to the office of the outside broker who sold the stock. The cheque was given as asked for and was promptly exchanged for notes, while the notes were on the same day converted into gold. It was not denied by Mr. BYNOE that he knew of the dividend warrants and other documents coming to his house, and that more than one of the envelopes relating to Miss POTTS'S business had been opened there. He asserted, however, and, we believe, still maintains, that he forwarded all Miss POTTS'S correspondence, with the exception of a certificate found upon him (as to which he offered an explanation), to the care of Mr. KIRK at a club of which that gentleman was a member. Mr. KIRK appeared as a witness at the trial of Mr. BYNOE, Miss POTTS being then dead and he being her residuary legatee and executor. He denied having received any of the letters containing the dividend warrants. Beyond this it was proved at the trial that the prisoner was in more or less embarrassed circumstances. The secretary of the London and Universal Bank gave evidence of Mr. BYNOE having come to that bank on three occasions with relation to dividends of Miss POTTS. He professed himself, according to the witness, to be acting on her behalf and he obtained money for the warrants. The witness admitted no doubt as to Mr. BYNOE'S identity. The accused was further identified by two witnesses from the outside broker who sold the stock referred to and who saw him on two occasions with regard to payment for it; while two well-known handwriting experts gave their opinion that the documents said to be forged were written by the writer of documents which were acknowledged to be in the handwriting of Mr. BYNOE. (With regard to expert evidence of this kind it will be remembered that it is intended for the guidance of the jury, who, however, have the veritable documents before them, with every opportunity of forming their own opinions from the study of them.) In short, so strong was the case against Mr. BYNOE upon the depositions taken before the magistrate that the two very experienced counsel engaged to defend him—Mr. C. F. GILLand Mr. A. H. BODKIN—urged him to plead guilty. This he resolutely refused to do, maintaining that Mr. KIRK was responsible for the forgeries. In these circumstances Mr. GILL and Mr. BODKIN, without absolutely retiring from the case, remained in court and took no active part in it further, we believe, than making suggestions to Mr. BYNOE while he defended himself. This very unfortunate course, taken no doubt in consequence of the prisoner's determination to accuse Mr. KIRK of the forgeries, prevented the witnesses from being properly cross-examined. Mr. BYNOE was convicted, and the sentence passed on him quite possibly owed much of its weight to the endeavour to implicate an innocent man.

It will be seen from the above brief account of the case that Mr. BYNOE, if not guilty, was the victim of a most extraordinary combination of damnatory circumstances. It is, however, a fact that at his trial he endeavoured to influence the jury by producing an anonymous letter which he had received in prison, and which professed to come from the actual forger; while it is also a fact that a young woman is now in existence who states that she wrote that letter to Mr. BYNOE and that she personally wrote the forged signatures of Miss POTTS testified by the two handwriting experts to have been written by the prisoner and that she went to the broker's office and personated Miss POTTS. This young woman, who is of the humbler classes, declares that she committed the forgery ignorant of the import of her act, at the instigation of a man of whom she then was fond, who was not Mr. BYNOE and who has wholly disappeared; and the fact that she was at the date of the forgeries on friendly terms with a man answering to her description is borne out by her father. It is, apparently, the theory of those now interested on Mr. BYNOE'S behalf that the crime with which he was charged was committed not by Mr. KIRK, but by someone who had intercepted the warrants said to have been forwarded to Mr. KIRK. It seems clear that if this young woman had given evidence at the trial that she was the author of the forgeries the jury would probably have believed her and would have acquitted Mr. BYNOE; while if they had further believed that she personated Miss POTTS at the broker's office in company with a man not Mr. BYNOE (or if the evidence insp'red them with doubt, which would have been sufficient) they would have also acquitted him of uttering the forged documents, knowing them to be forged. The matter at present stands as follows. Many persons in a position to judge, including, we believe, officials at the Home Office, are of opinion that the experts' evidence in the matter of the handwriting was wrong and misleading, and that the young woman was possibly the writer of the forgeries. What, however, the General Medical Council would have been called upon to decide was a much more complicated question, involving issues far too numerous and intricate to be given even in outline. They would have had to say whether Mr. BYNOE, who, on his own showing, must have acted with almost incomprehensible imprudence and want of good sense, had been the victim of a concatenation of compromising coincidences as well as of a foul conspiracy. It is impossible to express enough sympathy for a man who, albeit in consequence of his own unbusinesslike conduct, becomes the victim of such a crime—for the guilt, if Mr. BYNOE be innocent, must have been deliberately thrown

upon him. It is also impossible not to wish that if he be innocent facts entirely exculpating him and inculpating the real offender may speedily be made known to his friends and by them to the Home Office. It is, however, another matter to wish the General Medical Council to hold an inquiry into such a story, and to sift evidence, already sifted by the Home Office, with a view to either confirming or disagreeing with the decision arrived at by the Home Secretary and his advisers. It was a foregone conclusion that the High Court would not order the General Medical Council to undertake such a task, and we think that the Council have shown proper discretion in not acting upon their own initiative in the matter of rehearing the case.

Annotations.

"Ne quid nimis."

THE TREATMENT OF OUR SICK SOLDIERS.

MR. W. BURDETT-COUTTS, in the capacity of a special correspondent to the *Times*, has sent to that paper a lurid account of the inadequacy of the preparations made for the medical care and nursing of the sick in our large army in South Africa. The amount of sickness which has manifested itself in all our camps has for some time been the subject of serious consideration among medical men, for, as we had occasion to remark a fortnight ago, the lists of daily casualties demonstrate only too plainly that we have not yet solved the problem of protecting large bodies of troops from the ravages of such diseases as enteric fever and dysentery. Mr. Burdett-Coutts's letter will produce upon the public more than the impression that medical knowledge is at fault in the presence of certain problems of epidemiology. He has levelled an indictment against the War Office, the gist of which is that no proper arrangements of any kind have been made for the care of the large number of sick which should have been expected in an army of 200,000 men. Who is to blame and to what extent, as well as how far all the statements are accurate, will certainly be discussed by the public and we trust by Parliament; and we may be allowed to hope that the department which has covered itself with glory in all its arrangements for dealing with the wounded will have been found not to have broken down so completely as Mr. Burdett-Coutts believes in its management of the sick. Probably Mr. Burdett-Coutts is ignorant of the extent to which the Commander-in-Chief's lightning strategy has dislocated the plans of the Royal Army Medical Corps. One thing is certain: for the War Office to quote any eulogistic words of Sir William Mac Cormac and Mr. Treves uttered upon their return two months ago from the seat of war will be no complete answer to the charges. The experiences of Sir William Mac Cormac and Mr. Treves enabled them to express very definite opinions upon the treatment of our wounded in South Africa, upon the way in which battle-fields were stripped, and upon the heroism of many members of the Royal Army Medical Corps, but the vast epidemic of typhoid fever now prevalent did not come within their purview. But when Sir William Mac Cormac and Mr. Treves have spoken of the same things as Mr. Burdett-Coutts medical men will know who is the more likely to have the necessary equipment for giving us the truth.

WORKHOUSE OFFICIALS AT VARIANCE.

EXCELLENT indeed has been the result of the operation of the circular upon workhouse administration issued by the Local Government Board in the year 1895, reference to which was made in THE LANCET at the time and on subsequent occasions.[1] The common practice at that time in workhouses all over the country for paupers to be employed to perform the duties of nurses in the sick and lying-in wards, or in any other part of the workhouse, has been abolished, and paid and qualified nurses and assistants have succeeded them. But the Local Government Board also insisted on the appointment of a superintendent nurse who should have sole control over the infirmary wards. The matron was still to be the matron of the workhouse, not excluding the infirmary, and the result has been in not a few cases that there have been differences of opinion between the nurses on the one hand and the master and matron on the other. At the East Preston Workhouse in West Sussex a long series of complaints preferred by the superintendent nurse has recently been investigated by the guardians, who expressed the opinion that the friction was only what might be expected when the Local Government Board insisted on the guardians appointing two authorities in the workhouse. At all events, unpleasantness of this kind amongst officers does not conduce to the thorough discharge of their respective duties. All the officers concerned have been supplied with a copy of the guardians' report.

THE ACCIDENT AT SLOUGH.

MR. W. BRAMWELL BOOTH, writing to the *Times* of June 25th, makes a sensible suggestion—namely, that there should be a third man on the footplate of the engine of an express train who should act as look-out. Mr. Booth argues that an express train should, like a steamship, have a captain who should keep a look-out for signals and who should issue orders to the engineers—who, in short, should let the driver drive. This is to our minds an excellent suggestion and so simple that, like most simple things, it is a wonder that nobody seems to have thought of it before. Of course, it would cost money, but we are sure that no railway shareholder would object to a slightly diminished dividend if he knew that by that means increased safety would be afforded to the travelling public and a necessarily terrible strain taken off the minds of a very noble and arduously worked set of men. Only the innovation should be made compulsory, if made at all, upon every company. The custom of running past distant signals in the hope that the home signal will be clear, or if not that the breaks will pull the train up, seems far too common and should be severely put an end to. In this particular accident, however, there was no intentional running past the signals. The driver in his evidence stated that he never saw the signals and must have lost himself. Nothing can foresee or prevent these occasional failures of mental power. They happen to the greatest minds, as for instance, to Napoleon at Waterloo in the great cavalry attack.

THE EXPEDITION OF THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE TO BRAZIL AND THE UNITED STATES.

THE expedition which has been organised by the Liverpool School of Tropical Medicine for the purpose of investigating the causes of yellow fever in the United States and Brazil will have the coöperation of the British Government. The committee of the school have received an intimation from the Marquis of Salisbury that he had asked the British Ambassador at Washington and Her Britannic Majesty's consul at Parà to obtain all possible facilities from the United States' and Brazilian authorities on behalf of the expedition. It is also pleasing to find that official invitations to the expedition to

[1] THE LANCET, April 13th (p. 945) and May 25th (p. 1326), 1895.

visit Washington have been received from the heads of the Medical Departments of the United States of America, and to visit Baltimore at the instance of the authorities of the Johns Hopkins University. The expedition, which consists of Dr. H. E. Durham (Grocers' Research Scholar) and Dr. Walter Myers (John Lucas Walker Student), both of Cambridge University, sailed from Liverpool on Tuesday, June 26th, for Canada, and will proceed thence to Washington and Baltimore. After conferring with the bacteriological experts in those two cities the expedition will proceed to New York and will sail from that port to Parà, their subsequent movements being guided by circumstances. Advantage will be taken of the opportunity to test still further the work of the Liverpool school in malarial fever carried on by Major R. Ross, I.M.S., and also to prosecute the study of dysentery. A public meeting was held at the Exchange Buildings in Liverpool on June 25th, which was presided over by Mr. Alfred L. Jones, the chairman of the Liverpool School of Tropical Diseases, to consider "what action should now be taken to press upon the Government the necessity for the amelioration of the conditions of life in West Africa and other tropical countries by improved sanitation, better water-supply, segregation of Europeans, clearance of bush near towns, the introduction of light railways to the mountainous districts, and such other means as science may direct." A motion to this effect was carried unanimously in an influentially attended meeting. It was also proposed: "That the Liverpool Chamber of Commerce be requested to coöperate with the School of Tropical Diseases, and to ask the Government to receive a joint deputation on the subject." In the evening, on the invitation of Mr. Alfred L. Jones, a company of gentlemen sat down to a banquet at the Adelphi Hotel to do honour to the members of Liverpool's third expedition to the tropics who were about to sail for the Amazon. The toast of "The Yellow Fever Expedition" was proposed by the chairman and seconded by Professor Osler of Baltimore, to which Dr. Durham and Dr. Myers suitably responded. The chairman referred to the high esteem in which the late Miss Kingsley was held by West African natives and he suggested that the proposed hospital in Liverpool for the treatment of malarial diseases should bear her name. Mr. Jones generously offered to head the subscription list with a donation of £1000. Other subscriptions, amounting to £1200, were also promised towards the erection of the hospital. It is proposed to build the hospital on some waste land near the Royal Southern Hospital.

FATAL CASES OF PTOMAINE POISONING.

ON June 19th an inquest was held at Plymouth touching the death of Mabel Elizabeth Starling, aged 20 years. This was the second death in the family as alleged from the same cause. A week previously to her death the deceased with eight other members of the family partook of pork for dinner. Of these nine persons "eight suffered from symptoms of poisoning, two had died, and one escaped entirely. Mr. Starling suffered in the slightest degree; Mrs. Starling suffered severely, but the symptoms went off quickly. One son escaped for 24 hours. The other children were taken ill at varying periods of from two to four hours after dinner but recovered during the night." The family had partaken of fish (gurnet) for breakfast, but since none of them were affected until after dinner it may reasonably be concluded that the fish was not the offending agent. No other cases of persons who had eaten pork from the same carcass being attacked have been reported, and since there was direct evidence that the meat when delivered to the family was to all appearance fresh and good it would seem in the highest degree probable that it became subsequently infected with micro-organisms. It seems strange that a number of people who have eaten of the same poisonou article of diet should be affected so differently as regards the period of onset of the symptoms, their degree of severity, and their duration. It must be borne in mind, however, that food may be poisonous in two ways: (1) from the direct irritant and toxic effects of animal alkaloids developed by the action of germs before the food is ingested; and (2) by the germs themselves setting up an infective process in the body and liberating during their culture the alkaloidal poison, just as in acute specific infective fevers. Writing on this subject Sir George Buchanan remarked: "The phenomena which were spoken of as food-poisoning are claiming an ever-growing evidence to be regarded as true infective diseases, as much so as was scarlet fever or tuberculosis. They have not been generally admitted into this rank (1) from the circumstance that some of them have seemed to be wanting in the incubation period, and (2) because they are rarely recognised as being transmissible from person to person." Thorough cooking kills the germs, but it does not destroy the animal alkaloids which they have formed. The poisoning is then a chemical one. On the other hand imperfect cooking fails to destroy the organisms, and so the individual is subjected to two influences—the developed alkaloid and the infective or fermentative process in his body. Now it is well known that the tissues, organs, and secretions of some people are more susceptible to the action of infective organisms than are those of others—"vulnerability," as it is termed—and thus it becomes abundantly clear why the results of implantation of the organisms should vary so extremely in different individuals. Moreover, as regards simple poisoning by animal alkaloids the effects will vary with the dose, with the empty or replete condition of the stomach, and with the rapidity with which the alimentary tract gets rid of the offending matter. Unfortunately, articles of diet—especially meat—which have become charged with animal alkaloids not seldom are free from noxious smell, and thus the warning given by the odour of putrescence is wanting. To avoid dangerous and even fatal consequences the meat should be examined to see that it is quite fresh and free from disease. It should be cooked early and thoroughly, and whilst kept in the raw condition it should be placed in healthy surroundings.

THE LECTURERS AND LECTURES AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND FROM 1810 TO 1900.

AMONG the various preparations which have been made in view of the now fast-approaching centenary of the Royal College of Surgeons of England a great many details of much historical interest will be found in a list of lecturers and lectures compiled[1] by Mr. Victor G. Plarr, the accomplished librarian of the College. The Hunterian Professors, by whom the "Museum Lectures" were delivered, have invariably been men of eminence in their respective subjects, and many of their discourses have been published in THE LANCET, the latest example being Mr. A. W. Mayo-Robson's three lectures on the Surgery of the Stomach, which appeared in our columns on the 10th, 17th, and 24th of March last. Surprising changes have occurred in the science and art of surgery and in most of the allied branches of knowledge since these lectures were instituted at the instance of the Government when the Hunterian collection was handed over to the College in the beginning of the present century. The first Museum Lecture was delivered on Feb. 13th, 1810, between which date and the following May 10th two courses of 12 lectures each were delivered, one on Morbid Parts and Surgery by Sir William Blizard and the other on Comparative Anatomy by Sir Everard

[1] Printed b Taylor and Francis, Red Lion-court, Fleet-street.

Home, Hunter's brother-in-law, assistant, and executor, who made use of Hunter's manuscripts committed to his care and afterwards burnt the originals. From that year to 1839 inclusive 21 courses of lectures on surgery were delivered successively by John Abernethy, Sir Anthony Carlisle, James Wilson, Sir Benjamin Brodie, Thomas Chevalier, Sir Charles Bell, George James Guthrie, Sir Henry Earle, and Frederick Tyrrell. A long interval then ensued, but in 1868 the lectures were resumed and have been delivered regularly ever since. The other division of the Museum Lectures—namely, the course on Comparative Anatomy—underwent fewer vicissitudes, and the able discourses of Joseph Henry Green, Sir Richard Owen, Thomas Henry Huxley, Sir William Flower, William Kitchen Parker, and others have worthily upheld the scientific position of British anatomists. Mr. Plarr does not confine himself exclusively to the Museum Lectures, but gives lists also of the Arris and Gale lecturers, the Erasmus Wilson lecturers, the Bradshaw lecturers, and others. His pages are of considerable interest to ourselves from his frequent reference to the use which he has been able to make of THE LANCET in tracing the details of the lectures in the first half of the century, and from his discovery that among the pupils, tickets issued in 1816 for Sir William Lawrence's course on Comparative Anatomy No. 144 G was assigned to Thomas Wakley, the Founder of THE LANCET.

PERFORATING ULCER OF THE DUODENUM.

THE *Boston Medical and Surgical Journal* of May 3rd contains an exhaustive paper on this subject by Dr. R. F. Weir. Summaries of all the reported cases (51) in which an operation has been performed are appended. The symptoms of a duodenal ulcer are, as shown by Schwartz, frequently very slight. In 20 out of 25 cases of perforation the patients had been apparently in good health or had been so slightly indisposed that they had not sought medical advice. In only five cases were there previously gastric symptoms. One patient was thought to be suffering from dyspepsia and two from gastric ulcer. The following are the usual symptoms of duodenal ulcer. The pain when characteristic occurs several hours after eating. It is situated just below the gall-bladder and may reach to the median line or to a level with the umbilicus. Frequently it is absent. Occasional pressure, particularly over the region to the right of the twelfth dorsal vertebra, elicits pain. Vomiting was present in 17 per cent. of the cases. It is of diagnostic importance if it occurs one hour or several hours after a meal. The vomited matter consists of disintegrated food which is often mixed with bile and blood. Jaundice is rarely present; it results from duodenal tumefaction or from cicatricial contraction of the orifice of the bile duct. Hæmorrhage occurs in about one third of the cases of non-perforating ulcers. Bleeding may take place from the mouth or rectum and may prove speedily fatal. The blood discharged by the bowel is usually tarry, but it may be of a bright hue. When perforation occurs great pain is usually felt in the epigastrium or to the right of that region. Occasionally it has been observed at the umbilicus and in the left side. Vomiting often follows the pain; it occurred in 28 out of 34 cases. Peritoneal symptoms rapidly develop with a tendency in some cases to be localised in the upper abdomen and on the right side, for fluids escaping from the duodenum flow at first between the liver and colon and thence along the ascending colon. In the diagnosis of perforation the situation of the early or initial pain in the right hypochondrium and the previous history of dyspeptic symptoms are of great importance. The treatment of duodenal ulcer is similar to that of gastric ulcer. If the diagnosis has been narrowed down to perforation of the stomach, duodenum, or gall-bladder, an incision from four to six inches in length should be made along the edge of the right rectus muscle, not reaching much above the edge of the liver. Dr. Weir recommends that this incision should be supplemented by a transverse one in its upper third, toward the median line, permitting division of the fascia covering the right rectus muscle, which latter is to be pulled to the left, exposing its posterior sheath and peritoneum, which are to be divided. A duodenal perforation is usually found on the anterior wall of the bowel. An attempt should not be made to excise the ulcer because this would occupy too much time. In seven out of nine of the successful cases only suturing was employed. Thorough cleansing of the peritoneum is important. If the extravasation is limited careful wiping of the affected portion of the peritoneal cavity is sufficient; irrigation is more suitable in extensive peritoneal inflammation. Tubes surrounded by gauze are the best drains. As regards the 51 collected cases the ulcer was recognised and closed in 25. In 13 operation was performed after 30 hours' delay and all were fatal; 12 patients were operated on immediately, of whom eight recovered.

INNOVATIONS AT THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THIS society has recently resolved upon several very important alterations in its regulations for dealing with papers which in the matter of liberality are far in advance of anything that has yet been done by any medical society of the first rank. Authors of papers may now submit them to the Royal Medical and Chirurgical Society with the assurance that there is no probability of their being publicly discussed and afterwards returned as unworthy of a place in the "Transactions," for every paper accepted for reading is *ipso facto* accepted also for publication in the "Transactions." This is good, but the other alteration is even more important and shows that the present Council is determined that one of the principal aims of the society shall be carried out in the most liberal spirit. Every paper read before the society may be immediately afterwards, that is, before it has been published in the "Transactions," printed in any other medical or scientific periodical, and thus contributions to medical science, instead of being kept back, as hitherto, for 12 months and then published in the "Transactions" (the circulation of which must necessarily be limited), may be given to the professional world immediately through the medium of the medical journals.

THE HOUSING OF THE WORKING CLASSES.

WE have from time to time called attention to the prominence which is now being given to the problem of providing the poor of our cities with sanitary homes—a problem the complete solution of which seems in some cases almost hopeless. The Local Government Board has now addressed a circular to local authorities calling their attention to the Public Health Acts of 1875 and 1891 and the Housing of the Working Classes Act of 1890, and stating that the Board is preparing digests of the portions of these Acts dealing with this subject, which will be forwarded in due course. As the present system of drafting Acts of Parliament, which complicates them with cross references to other Acts already in existence, prevents any Act from being, by itself, a guide to those desiring to make use of its provisions, these digests will no doubt be extremely useful. Beyond promising these the Board of Trade circular contains a reference to the Bill now before Parliament which amends the portion of the Housing of the Working Classes Act that enables local authorities to build new dwellings for the working classes of their districts, but does not go further into this branch of the matter, owing, no doubt, to the fact that legislation on the subject is proceeding. The circular,

however, gives a full and instructive summary of the powers possessed by local authorities to inspect existing houses, abate nuisances, close houses where necessary, and procure the punishment of owners of insanitary premises, and in other ways to protect the poor within their gates; while by its language it emphasises the fact that the powers given to these authorities by statute do not only enable them to do certain things but impose upon them duties which they neglect if they do not acquaint themselves with their powers and proceed to act under them where anything exists to call for action. Acts of Parliament of this class, as we know—the Inebriates Act being an example which will occur to many—are not always acted upon with promptitude by local bodies, and as far as the Imperial Government is concerned circulars such as that before us constitute presumably the only method by which it can contribute to the enforcement of such Acts after it has once placed them on the statute-book.

THE HOWARD MEDAL OF THE ROYAL STATISTICAL SOCIETY.

THE next competition for the Howard medal will take place in the ensuing session of the Royal Statistical Society. The subject of the prize essay is "The History and Statistics of Tropical Diseases, with especial reference to Bubonic Plague." Essays must be sent in on or before June 30th, 1901, subject to the following rules:—

Each essay to bear a motto and to be accompanied by a sealed letter marked with the like motto and containing the name and address of the author; such letter not to be opened except in the case of the successful essay.

No essay to exceed in length 100 pages (8vo) of the *Journal of the Royal Statistical Society*.

The council shall, if they see fit, cause the successful essay, or an abridgment thereof, to be read at a meeting of the Royal Statistical Society; and shall have the right of publishing the essay in their *Journal* one month before its appearance in any separate independent form; this right of publication to continue till three months after the award of the prize.

The President shall place the medal in the hands of the successful candidate at the conclusion of his annual address at the ordinary meeting in November, when he shall also re-announce the subject of the prize essay for the following session.

Competition for this medal shall not be limited to the Fellows of the Royal Statistical Society, but shall be open to any competitor providing the essay be written in the English language.

The council shall not award the prize except to the author of an essay, in their opinion, of a sufficient standard of merit; no essay shall be deemed to be of sufficient merit that does not set forth the facts with which it deals—in part, at least, in the language of figures and tables; and distinct references should be made to such authorities a may be quoted or referred to.

Further information can be obtained from the assistant secretary, Mr. B. W. Ginsburg, at the office of the society, 9, Adelphi-terrace, London, W.C.

THE CAUSE OF CARIES OF THE TEETH.

IN a recent publication[1] Dr. Sim Wallace has advanced an ingenious theory to account for the increasing prevalence of dental caries. His views are as follows:—"The cause of the prevalence of dental caries is that the natural food-stuffs are to a large extent riddled of their accompanying fibrous parts and prepared and consumed in a manner which renders them liable to lodge and undergo acid fermentation in the mouth, while from this same cause and the induced conditions the micro-organisms of the mouth lodge and multiply and augment the rapidity and intensity of the acid fermentation." That the preparation of our food-stuffs may in some small measure assist in the production of caries seems possible, but that it is "the cause" is highly improbable. Much of Dr. Wallace's reasoning is unsound and many of his statements are incorrect. He crosses arms with those investigators who maintain that the teeth are degenerating in some unknown way and so are unable to resist the action of the acids set up by fermentation in the mouth. He prefers to hold the view that the cause is to be found in the food-stuffs being prepared in a manner which makes them more apt to lodge in the mouth, and he makes the statement, quite unsupported by any data, that the "teeth of the present day are as perfectly formed from a chemical and microscopical point of view as are the teeth of those races which are practically free from caries." That the structure of the tooth plays a most important part in the resistance to caries is within the knowledge of a dental practitioner with even a small experience. For example, in mouths where there is but a slight amount of caries, and that slow, the enamel of the teeth is generally hard and resistant to the instrument, while where caries is prevalent and rapid the reverse is the case. Indeed, it requires but little observation to show that there is something, so far not recognised or understood, which plays a most important part in the liability of teeth to be attacked by caries. Crowding of the teeth is a fruitful predisposing cause of caries and this is acknowledged by Dr. Wallace, but he attributes the crowding to want of development of the tongue from lack of fibrous material in the food-stuffs. The removal of this fibrous material from the food stuffs robs the tongue of a certain amount of activity and so interferes with its development. Here, again, as with nearly all his statements, no data are given in support of his contentions. The true cause of caries has yet to be discovered and is not quite so simple as Dr. Wallace would lead us to believe.

[1] The Cause and Prevention of Decay in Teeth. London: Messrs. J. & A. Churchill.

AN UNQUALIFIED PLAINTIFF UNDER THE MEDICAL ACTS.

A CASE heard recently in the Stourbridge County Court seems to have raised a question under the Medical Act of 1858 arising out of circumstances not contemplated by those who framed the statute. The plaintiff suing for fees for medical attendance was not a registered medical man. He was a medical student who while pursuing his studies had employed a qualified practitioner to keep alive the practice which he (the student) had inherited from his deceased father. The fees, therefore, had been earned by a qualified man but the person bringing the action was not on the Register, and the Act above referred to says that "no person shall be entitled to recover any charge in any court of law for any medical or surgical advice ..... unless he shall prove upon the trial that he is registered under this Act." This seems fairly explicit, but the Act was, according to its preamble, passed in order that "persons requiring medical aid should be able to distinguish qualified from unqualified practitioners," and the intention of the legislature was no doubt primarily to hinder unqualified persons from holding themselves out to be medical men and exercising medical functions. There is no direct authority as to what is to happen where a duly registered medical man has earned the fee and a lay employer has sued for it, but there can also be no very strong reason why the section we have cited above should not be construed literally in such a case. It is possible that those who passed it may have intended to stop by it any intervention whatever by laymen in matters connected with medical practice, while perhaps they contemplated a system of laymen farming the work of qualified medical men which might otherwise arise. In the case at Stourbridge no decision was given on this question by the county court judge, as he pointed out that should he decide it in the defendant's favour the only result would be that the qualified medical man would sue instead of the then plaintiff, and the objection was accordingly dropped. A case, however, might well arise in which, owing to some dispute between employer and employed, the man who had earned the fee might not be willing to aid in recovering it, and even if such a state of affairs as we have described may not

be likely to occur frequently we should have liked to see the law on the matter clearly laid down.

ANTI-STREPTOCOCCIC SERUM IN CEREBRO-SPINAL MENINGITIS.

WE learn that in an epidemic of cerebro-spinal meningitis at Jerusalem 12 patients were treated with Marmorek anti-streptococcic serum and all recovered. In a disease so fatal as cerebro-spinal meningitis it is allowable to employ any treatment in reason even though there is not much probability of its success. We must confess that *a priori* we should not have imagined that anti-streptococcic serum would have proved efficacious against an entirely distinct micro-organism such as that giving rise to this form of epidemic meningitis.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: MEETING OF FELLOWS.

THE annual meeting of Fellows will be held next Thursday, July 5th, at 5 P.M., and it is desirable that a quorum should be present, otherwise it is possible that these meetings of Fellows may be discontinued altogether. Already one meeting a year has been done away with and no quorum has been obtained since July, 1897. The agenda paper includes three motions by Mr. R. B. Anderson relating to various matters of interest. We may mention also that the additions to the museum during the past year will be on view in the Council Room on July 3rd, 4th, 5th, 6th, and 7th.

VACCINATION FEES AT BURY.

AT the meeting of the Bury Board of Guardians on June 7th the reply of the Local Government Board to a letter from the guardians as to the fees payable to the public vaccinators was read. The principle on which payment is made is stated to be that "their remuneration should mainly depend on the fees which they received for successful vaccination," so as to give every inducement to promote, as far as possible, the vaccination of all children. Under the new system of domiciliary vaccination the board introduced the fees provided for under article 3 (1) (2) of the Vaccination Order of 1898. "The board decided that while the former should not be less than 1*s*. per case it should not exceed one-third of the fee payable for each case of successful vaccination." The guardians decided to pay 1*s*. 8*d*. and 5*s*.

CHOREA: A STATISTICAL AND CLINICAL STUDY.

PROFESSOR ALLEN STARR of New York contributes a valuable paper on the above subject to the volume of the *Festschrift* in honour of Dr. Abraham Jacobi, just published (May, 1900), analyses the histories of 1400 cases of chorea seen in the Vanderbilt Clinic. The proportion of females compared with male patients was almost exactly as 2 to 1, and it appeared that the disease was relatively common among children of the poorer classes and was often accompanied by anæmia. The most constant physical condition accompanying the disease was malnutrition. Among etiological factors preceding the disease fright was noted in 285 cases, and a history of acute rheumatism in 290. Organic cardiac murmurs were observed in 175 cases and functional or hæmic murmurs in 123 cases. In 871 patients no cardiac murmurs could be found. As regards age, 919 cases, or 65 per cent., occurred between the ages of seven and 14 years. As regards seasons, it was recorded that 707 out of 1129 cases occurred between March and August. The choreic movements were general in 951 cases and unilateral in 449, the right side being affected slightly more than the left. Mental changes were observed in 827 cases in the form of irritability combined with more or less dulness, and speech was affected in 556 cases. Therapeutically it appeared that arsenic given in increasing doses and pushed to its physiological limit gave the best results. The dose had to be reduced slightly after this. Antipyrin was also used with favourable results, but very little benefit was obtained from exalgin, paraldehyde, phenacetin, or the bromides. A change of air to counteract the anæmia and to add freshness to the patients' surroundings was attended with the most beneficial results.

THE INTERNATIONAL MEDICAL CONGRESS, PARIS, AUGUST, 1900.

ALL members of the profession, including ladies and dentists, who wish to become members of the Thirteenth International Medical Congress are requested to send in their names by return of post to the secretaries of the National Committee for Great Britain and Ireland (Dr. A. E. Garrod, 9, Chandos-street, Cavendish-square, London, W., and Mr. D'Arcy Power, 10A, Chandos-street, London, W.). The list of members in Paris will close on July 15th, and after that date it will be impossible to guarantee any of the privileges of the Congress to those who send in belated applications. A ladies' committee has been formed under the auspices of Mesdames Lannelongue and Brouardel and a convenient room has been placed at their disposal. The list of entertainments is completed by the announcement of a grand fête to be given by the Town Council of Paris in the Salons of the Hôtel de Ville on the evening of August 7th.

THE WATER-SUPPLY OF MANCHESTER.

THE water-supply of our towns becomes more and more difficult as the population grows, and where it is abundant to-day there is anxiety as to to-morrow. This is illustrated by the history of the Manchester supply. When the Longdendale reservoirs were completed it was thought that the provision made was practically inexhaustible, but after a time it became evident that more than the 25,000,000 gallons which it now gives would be wanted, so the Thirlmere scheme was gradually worked out and one pipe laid, when for a time there was the pleasant feeling of abundance and security. Since that day, however, there has been, according to the report of the Waterworks Committee which is to be submitted to the Council at their next meeting, "a very excessive increase in the consumption." The committee wish the public to get rid of the idea that there is "an exhaustless supply for all time," to avoid waste, and to practise a reasonable economy in the use of water. The present consumption is about 32,000,000 gallons per day, "and the increase during the last 10 years has been at the rate of over 1,000,000 gallons per day per annum." With the additional pipe which it is proposed to bring from Thirlmere it is calculated that the total quantity obtainable from that source will be 50,000,000 gallons daily, which with the Longdendale supply is estimated to make up 75,000,000 gallons per day. With the increasing growth of habits of personal cleanliness which are gradually permeating through the population from above downwards there is a much greater demand for water for domestic purposes, including the supply for baths which are now common in Manchester in small "weekly" houses, as they are called, than would have been dreamt of 50 years ago. The committee have come to the opinion that at the rate of increase for the last 10 years and allowing for the growth of the population "the whole 75,000,000 gallons per day is likely to be overtaken in about 35 years. They therefore feel it their duty to make this emphatic statement so that all citizens and consumers may realise their personal responsibility for the proper and moderate use of the water." While it is absolutely necessary to give water to the towns it ought not to be forgotten that many country places all

through the island suffer from a chronic water famine and means will have to be taken for their relief.

THE MIDWIVES BILL.

THERE was a debate, which will be found fully reported in our columns on p. 1920, in the House of Commons on Wednesday evening last upon this measure. Mr. Griffith-Boscawen moved that the Bill be considered upon that day three months on the grounds that it had been inadequately discussed on its second reading and rushed through the Standing Committee. Colonel Milward, in seconding the amendment, thought the measure too drastic. Sir J. Batty Tuke, in a successful maiden speech, approved the general lines of the Bill, though he considered that it should be amended in certain particulars. Dr. Farquharson thought the measure had been sufficiently discussed, but Sir Walter Foster urged postponement, pointing out that the measure should be dealt with by the Government of the day, the question involved being too large to be dealt with by a private Member. While Mr. Heywood Johnstone was falling in with this view 5.30 o'clock was reached and the debate stood adjourned—probably for the rest of the session, as Government has taken all the available time.

THE DEARTH OF MEDICAL ASSISTANTS AND ASSISTANT CURATES.

THE *Westminster Gazette* states that a vicar in the Midlands recently applied to five theological colleges for an assistant curate in priest's orders and was unable to obtain one. In our own profession the dearth of assistants has of late years become very marked, but there are obvious reasons for this. First comes the action of the General Medical Council in forbidding the employment of unqualified men, and this is an influence which will abide. Secondly, the war in South Africa has absorbed numerous younger members of the profession who would in all probability be holding assistants' posts if they were not engaged in minimising the necessary horrors of war. The reasons for an ecclesiastical scarcity are not so obvious. Possibly ideals are higher nowadays than they were 60 years ago and the class of man who used to take orders because it was a calling which carried with it a certain social position and a comfortable income has become smaller. Perhaps, too, the fact that the comfortable income has become smaller has something to do with the matter. But however this may affect the average assistant curate whose field of labour is a country parish we fancy that town incumbents who live with their assistants in a clergy house find no difficulty in getting men willing to live and work with them without any thought of the amount of their salary, provided that they are fed and have fairly comfortable quarters.

SMALL-POX AT STALYBRIDGE AND SALFORD.

IT may be remembered that small-pox was taken to Stalybridge on April 28th by a man returning from Russia. Up to June 6th there had been 18 cases and three deaths. The first death was that of the man who introduced the disease and the other two were those of two boys who were unvaccinated. A sub-committee of the Town Council has been appointed to consider the question of providing an infectious diseases hospital and to deal generally with all matters of emergency relating to persons suffering from small-pox. It appeared, the mayor said, from inquiries he had made, that small-pox was not subject to the quarantine laws, which only applied to cholera, to plague, and to yellow fever. He suggested "that action should be taken with a view to bringing small-pox within the operation of the quarantine laws." It was decided that the mayor, the town clerk, and the medical officer of health should go as a deputation to the Local Government Board "with a view to get the matter dealt with in an omnibus Bill at the end of the session." Salford also has had an outbreak of small-pox. Recently Mr. C. H. Tattersall, the medical officer of health, reported that five cases had been brought under his notice. Prompt measures had been taken to check the spread of the disease. So far Manchester has escaped.

THE PROPHYLAXIS OF PLAGUE.

La Salud, a monthly review of hygiene published at Buenos Ayres, contains in its March number an interesting article upon plague. Formerly, says *La Salud*, according to a tradition common amongst certain tribes of South-American Indians, wide-spreading fires used to sweep over the land. The inhabitants were in the habit of taking refuge in caves and dens of the earth. From time to time they poked out the branch of a tree and if this when pulled in again showed no signs of burning they considered it safe to come out. So formerly when plague ravaged and desolated various countries the inhabitants shut themselves up in the cave of isolation and did not come forth until they learned that plague had disappeared. Nowadays, however, just as the Indian tribes possess herds of horses which they did not formerly possess and are able by these means to stamp out pampas fires, so that there is no need to take refuge in a cave, so also modern cities possess hygienic knowledge and conditions which render isolation unnecessary and a general dissemination of plague throughout Europe or America is as impossible as a fire which should affect the whole pampas. In India and in China only those persons succumb who live under grossly unhygienic conditions. With reference to the recent outbreak of plague in the Argentine the article continues: "It would be greatly to the honour of the Argentine Republic if she would invite other countries to a conference to consider the question of meeting plague, if not actually by abandoning all international action yet by leaving commerce perfectly free and by treating the disease wherever it appears exactly like any other infectious disease which assumes endemic characters."

TICK FEVER IN NEW SOUTH WALES.

DR. FRANK TIDSWELL, Principal Assistant Medical Officer to the Government of New South Wales, has issued a second report upon Tick Fever. This report, which is dated February, 1900, is really a continuation of his first report which was dated December, 1898, and upon which we commented in our issue of May 6th, 1899, p. 1240. The first report dealt with the immediate effects of protective inoculation and the second takes up the tale and gives an account of the result of exposing an inoculated herd to the influence of ticks. The experiments were made at Greenfell, Rockhampton, in Queensland, a district seriously affected with ticks. The total number of animals used was 60—namely, 22 inoculated and eight controls from New South Wales, and 20 inoculated with 10 controls from the North Coast District. Of the inoculated animals five escaped entirely and eight died, but although these eight may be said to have died from causes incidental to their exposure to ticks none of them could be said to have died from tick fever *per se*. Among the control animals eight died, four from acute tick fever, one from debility following tick fever, and three from causes incidental to their exposure. As a rule, the symptoms were much less severe in the inoculated than in the control animals, although in six of them the disease was nearly as severe as in the control animals, and of these six four died, three of which were, however, old and unhealthy to start with. Dr. Tidswell concludes that the main line of defence lies in keeping the ticks out of

the colony, but inoculation may be of great service, for it does not involve permanent ill health; inoculated animals resist second inoculation attacks and, as was seen by the experiments, they take the fever much less severely than does an uninoculated control. Careful dipping is of great use. With regard to the selection of blood for inoculation its infectivity does not depend upon controllable factors. The blood of one animal will give good reaction 12 months after inoculation, while that of another will be useless shortly after three months.

THE FIRST PRINCIPAL OF THE UNIVERSITY OF BIRMINGHAM.

IT is announced that Oliver Joseph Lodge, F.R.S., LL.D., D.Sc., has been appointed the first principal of the new University of Birmingham. It is difficult to know whether to congratulate most the new principal upon the honour so rightly offered to him or the new University upon his acceptance of the post, but that both parties to the transaction are to be felicitated there can be no doubt. Dr. Lodge was educated at the Newport (Salop) Grammar School and at University College, London. In 1877 he took the degree of D.Sc. at the University of London, gave lectures on physics at the Bedford College for Ladies, and was appointed Assistant Professor of Physics at University College, London, where, during Professor Clifford's illness, he took charge of his classes. In 1880 he was appointed Professor of Physics at the then newly-established University College, Liverpool. He has written upon Electricity and Light, and his "Modern Views on Electricity" is perhaps the clearest account of a by no means easy subject which has appeared up to the present time. He has also made researches into the nature of lightning and lightning discharges and has also written upon Herz and his work. Apart from the more purely scientific subjects Dr. Lodge takes a deep interest in those somewhat obscure phenomena known as psychic. He is a prominent member of the Psychical Research Society and was one of those appointed to examine into the phenomena presented by Eusapia Palladino.

THE FAMINE AND SPREAD OF CHOLERA IN INDIA.

THE events taking place in China and in South Africa, to say nothing of those on the West Coast of Africa in the relief of Kumasi, occupy such a prominent place at the present moment as to absorb almost exclusively all public thought and attention. It is natural that it should be so, but the lamentable loss of life and the suffering entailed by these events are really insignificant compared with the truly deplorable state of affairs in India at the present time as set forth, for example, in a communication from the special correspondent of the *Standard* of June 26th. India has of late years been a prey to all the ills that can afflict a country. More direct and terrible even than the fear of starvation is the fear of cholera, and we are confronted with the sad and remarkable spectacle that the unfortunate and starving natives are being driven from many famine relief centres by the dreaded scourge of cholera in order to meet their end in a slower and less agonising way than that disease often causes; whereas in all the districts of India wherein cholera has not appeared distress compels them in increasing numbers to seek and hold on to the famine relief works as their only chance. Nor is this all. The want of water and the fear of a water-famine, the enormous mortality amongst both man and beast, and the extreme poverty and increasing enfeeblement of the native population make up an appallingly realistic picture of human suffering. The condition of the Rajput States, of the Bhil country, and of Jodhpur State, where over a million beasts have died from starvation, and of other extensive parts of India is simply terrible.

SIR WILLIAM GAIRDNER was entertained at dinner in Glasgow on June 19th with many evidences of sympathy and enthusiasm, the occasion being his retirement from his professorship in the University. The company numbered about 140, Principal Story, of the University, being in the chair. Sir William Turner, replying to the toast of "The Medical Profession," which had been proposed by Sheriff Berry, stated in the course of his remarks that after Sir William Gairdner had withdrawn from his duties as professor in Glasgow University he (the speaker) would take his place as the oldest teacher in a Scottish university, 40 years having elapsed since he commenced to teach anatomy in Edinburgh University. Sir William Gairdner, replying to the toast of his health, proposed by Principal Story, said that his arrival in Glasgow marked almost to a month the middle point of his life. He was 38 years of age when he became a professor and he had lived for 38 years afterwards. If he put to himself the question whether the former or the latter 38 years were more fraught with real happiness he should be puzzled to give an answer, but on the whole he thought he should prefer the latter period. The toast of "The Lord Provost and Corporation of Glasgow" was proposed by Sir Hector C. Cameron and acknowledged by Lord Provost Chisholm.

IT has been found convenient to postpone the Malaria Conference which it was proposed to hold in Liverpool at the end of July, the centenary celebration of the Royal College of Surgeons of England and other events in the medical and scientific world having been arranged for the same time.

SIR WILLIAM BROADBENT will formally open the new Clinical Museum at the Medical Graduates' College on Wednesday next, July 4th, at 8.30 P.M., when Professor Osler, F.R.S., of Baltimore, will deliver an oration on "The Teaching of Practical Medicine."

THE Guy's Hospital Biennial Dinner will be held at the Whitehall Rooms, Hôtel Métropole, on Friday, July 6th, at 6.30 P.M., under the presidency of Mr. Charles Higgens.

THE WAR IN SOUTH AFRICA.

THERE is still a pause in Lord Roberts's operations, for what has been recently taking place, although of a sufficiently stirring nature, is not likely to have any serious influence on the course of events. Notwithstanding that the Boer forces have exhibited unwonted activity of late and have had some successes the campaign is slowly but surely coming to an end—if it has not virtually already done so. General De Wet is commanding, however, with remarkable skill and success in his operations against our lines of communication between Kroonstad and the Vaal river. If it be true, as is reported of this Boer general, that he declared he would make Lord Roberts repent of having refused to accept his terms of surrender, he has done a good deal to justify his threat, for his force, owing to its astonishing mobility, has of late been apparently ubiquitous. A recital of the raids, surprises, and exploits of General De Wet reads like an exciting chapter in a book describing the adventures of some notable guerilla chief. By his energy and enterprise he has damaged the railway about Rhenoster river, captured the Derbyshire Militia, inflicted considerable loss on the Devonshire Militia, attacked a post at Honing Spruit and burned three wooden bridges, and succeeded in capturing several convoys with their wagons, stores, and ammunition, including one sent to the Highland Brigade.

It was at the last-named engagement that Colonel Bullock of the Devon Regiment, undaunted by his previous experiences, behaved with such stubborn pluck and that Mr. Lenthal Cheatle, who happened to be present in the train, had the opportunity of rendering very important services to the wounded. It will naturally be the first aim and object of Lord Roberts to see whether he cannot put an end to this eventful history by cutting off and capturing this force and its wily leader. We may confidently expect to hear soon of some active, and, let us hope, decisive, movements on the part of the British forces in the Transvaal.

So far for the military situation at the present time. Turning to the medical history of the war we may briefly allude to a communication which appeared in the *Times* of June 25th descriptive of the experiences of Dr. Morris Martin with General Cronje and the Boer forces until he obtained permission to go to Delagoa Bay, where he seized an opportunity for making his escape to this country. As the communication gives a description of what was going on behind the scenes with the Boers whilst the war drama was actually taking place it is worth reading.

The health of the British troops as a whole is stated to be good and their spirits are all that could be desired. There is still, however, a terrible amount of enteric fever prevalent among the army in the field and also (although to a far less extent) dysentery, together with many cases of pneumonia and diseases of the respiratory organs. A very large number of men are in hospital at Bloemfontein suffering from enteric fever. Large batches of sick and wounded are arriving from time to time in this country and reinforcements are in like manner being sent out to South Africa with *personnel* and *matériel* for the various hospitals, military and otherwise. According to a return just issued by the War Office the total losses since the beginning of the war up to the end of last week (exclusive of sick and wounded men now in British hospitals in South Africa) amounted to 26,296. The details are as follows:—

—	Officers.	Non-commissioned officers and men.
Killed in action	250	2384
Died from wounds	68	589
Missing and prisoners (excluding those who have been recovered)	37	1650
Died from disease	125	3985
Accidental deaths	—	66
Sent home as invalids	784	16,358
Total	1264	25,032

We notice that according to a communication from the special correspondent of the *Standard* at Cape Town, dated June 25th, it is alleged that during the last few weeks there has been a growing feeling of dissatisfaction on the part of both the public and the patients with the way in which the military hospitals and convalescent wards are being managed. The whole matter was discussed at a meeting of the Good Hope Society for the Aid of the Sick and Wounded. The Archbishop of Cape Town brought forward statements in regard to Rosebank Hospital to the effect that invalids were insufficiently supplied with warm clothing, while other statements were made that the food was insufficient in some cases, and in others of a nature unsuitable for patients suffering from dysentery or enteric fever. The Archbishop brought forward a motion drawing the attention of the military authorities to the great neglect in the supply of proper clothing and food, but subsequently withdrew it on a representation that the matter would be given full publicity in the press. The Rev. Mr. M'Clure urged that a report should be drawn up, contending that those found responsible for neglect should be very severely dealt with. The matter has been left in the hands of a committee, and the Archbishop of Cape Town is stated to have apologised for having made statements founded upon erroneous information. We must be content to suspend our judgment until the result is made known.

We have referred elsewhere to the communication from Mr. W. Burdett-Coutts, M.P., which appeared in the *Times* of Wednesday, June 27th. The accuracy of Mr. Burdett-Coutts's statements will be tested immediately.

WITH THE IMPERIAL YEOMANRY HOSPITAL.

(FROM A SPECIAL CORRESPONDENT.)

The winter has come upon us now with its black frosts. The days are much colder than on our arrival at Deelfontein, when the most comfortable uniform was merely a flannel shirt and trousers without any coat. Now the medical officers are often glad to make their rounds in top coats as well as to wear their warm winter underclothing. Life in tents has its drawbacks and one often longs for a more stable edifice in which a blazing fire could warm one's half frozen hands and feet. Although the thermometer does not register any great degree of cold the wind seems much more piercing here than in England, and one never feels warm unless the sun is shining brightly. At night black frosts occur, the absence of white hoar frost being due to the extreme dryness of the atmosphere, and we occasionally find that the water for our morning tub is covered with a layer of ice a quarter of an inch thick. It requires some amount of determination to take a bath in water like this and when exposed to a biting wind. The rainy season has been an exceptionally long one this year, and only last week very heavy showers fell for three days. These rains are very heavy while they last and are as a rule accompanied by thunder and lightning.

The general health of the hospital encampment remains good and the patients still continue to pick up their former health, and in some cases with an astonishing rapidity. So far, with one exception, none of the sisters has fallen seriously ill. Apart from minor ailments, such as sore-throats or toothache, their bill of health is a clean one. We all regret that one of the sisters, who was suffering from necrosis of the superior maxilla when she started from Scotland, has since been invalided home.

A few cases of scarlet fever have occurred in the camp, but by the most careful isolation Dr. J. W. Washbourn has been enabled to prevent its spread. The origin of the scarlet fever was found to be a patient who came from Naauwpoort Hospital and who was found to be "peeling" after having suffered from a sore-throat a week or two before. He passed the infection to the orderly who was attending the sick in the hut in which he was located, and one or two patients and orderlies have also since caught the infection. This has entailed considerable trouble and has necessitated the disinfection of the tents and huts in which the cases were discovered, together with the transference of the patients to other huts during the disinfection. Colonel A. T. Sloggett, R.A.M.C., has also arranged for two small separate encampments, one where the cases of scarlet fever are nursed and a second one where the men who have been exposed to infection can be put into quarantine. By these methods the disease has been stamped out and only a very few cases have occurred.

Of more serious import is the occurrence of typhoid fever and dysentery amongst some of the medical staff and a few of the orderlies and patients. Dr. R. T. FitzHugh[1] and Mr. Greenfield and Mr. Hobart, the store-keeper, are down with enteric fever, and one misses them sorely, for Dr. FitzHugh was acknowledged to be the best singer in the camp. His comic songs were unequalled and at every concert "We 'ad a roarin' time" was eagerly called for. Whilst one regrets that cases of these diseases should arise within the camp itself one must realise the immense difficulty of treating 300 or 400 patients suffering from typhoid fever and absolutely preventing any spread of infection when any single piece of soiled linen or any one patient can spread the disease indefinitely if any neglect of rules occurs.

All the huts are now completed and we have about 700 patients in the hospital at the present time. The camp is assuming the appearance of a small model village with its level well-kept streets, plainly marked out with a continuous row of whitewashed stones on each side of the roadway. 70 more tents are to be sent up from Cape Town and they will afford accommodation for 500 more patients. The medical cases far exceed in number those of a surgical nature and several of the surgical officers are giving assistance on the medical side of the hospital. The number of medical cases is larger for two reasons, chiefly because owing to the small amount of resistance offered by the Boers there have been very few casualties on our side lately, and also because convalescence in medical cases is a longer business than it is in surgical ones.

[1] We regret to say that Dr. R. T. FitzHugh, to whose illness our correspondent alludes above, died on June 15th, as announced in our last issue, p. 1830.—ED. L.

At present nothing very definite has been arranged by Colonel Sloggett, but it has been suggested that another branch hospital should be started. At first Surgeon-General W. D. Wilson, the principal medical officer, thought that the most suitable place would be at Kroonstad, but now, owing to our rapid advance and the occupation of Johannesburg and Pretoria by the Imperial forces, the necessity for a hospital there has disappeared. For strategic reasons it is now far more likely that Pretoria would be the more appropriate site for an advanced hospital, but it is quite possible that Maitland may be chosen in the hope that the staff of the Imperial Yeomanry Hospital may be able to be as near as possible to the probable camp of the Yeomanry forces when they collect again at Cape Town on their way home.

On the medical side of the hospital there are practically three diseases in evidence—typhoid fever, dysentery, and rheumatism. The hardships of campaigning without shelter against the rain and cold biting winds and with insufficient rations seem to have played a most important rôle in the etiology of dysentery and rheumatism. In many cases it is found that an attack of dysentery commenced after a soldier had been exposed without tents for three nights to wet weather, being obliged to allow his clothes to dry on him during the next day's march. This exposure may lower the vitality of the intestines and so render the man more liable to infection with the amœba of dysentery which would be repeatedly drunk in the dirty water with which he had slaked his thirst on the march.

A typical case of dysentery begins with a little diarrhœa, three or four motions on the first day, and with little or no rise of temperature. The number of motions on the second and third days reaches from 10 to 40 or 60, according to the severity of the case, and large quantities of red blood and mucus are passed, although each evacuation may be only small in amount. In untreated cases and in cases which resist treatment the diarrhœa increases until the patient requires the bed-pan almost continuously. There is severe abdominal pain and much rectal straining and discomfort. The stools are often very offensive and in older people may give rise to a suspicion of cancer of the rectum. The spleen is sometimes slightly enlarged in dysentery and may cause difficulty in excluding suspicions of typhoid fever. We have had no cases of abscess of the liver resulting from dysentery so far. The temperature chart is more or less typical and its variation may be given from an actual case which was proved by post-mortem examination to be one of dysentery. The temperature rises each evening about a degree until a temperature of 101° or 102° F. is reached and falls each morning, sometimes to normal, then a period occurs in which the temperature is about 101° each evening and normal in the morning. As the patient improves his temperature again gradually falls in the evening until the normal temperature is reached and maintained. Should chronic diarrhœa persist the temperature generally registers 99° in the evening. The temperature does not always vary with the severity of the diarrhœa. The treatment adopted is to give large doses of powder of ipecacuanha, from half a drachm to one drachm at a time for several doses, every four hours until the bleeding and diarrhœa stop, and then to continue with opium and bismuth. Great care is required in this treatment to prevent obstinate vomiting. It is advisable to keep the patient in bed and to give from 15 to 30 drops of laudanum by the mouth in a little water an hour before each powder, and also to administer a very little plain milk only whilst the ipecacuanha treatment lasts. It is of the utmost importance to commence the treatment early and to give large doses of ipecacuanha, as if the diarrhœa once becomes almost continuous nothing seems to be of any assistance to the patient and he gradually sinks and dies. His pulse fails, and in a few days his condition becomes most wretched. Continuous and uncontrollable diarrhœa quickly emaciate him, his appetite goes, he is listless and apathetic, and may have lost full consciousness of what is going on around him. He becomes a misery to himself and to those who attend on him. Rudyard Kipling well describes dysentery as the disease "which eats the heart out of a man." No improvement seems to take place in the amount of diarrhœa for the first 24 hours after the commencement of the ipecacuanha treatment but the patient is much more comfortable and blood is generally passed in smaller quantities. The treatment with sulphate of magnesia and sulphate of soda has also been tried. It seems useless unless the treatment is begun quite early, and as it is also apparently very exhausting and depressing it is advisable not to try it in the last stages of the illness. Young, robust men stand it best. Drachm doses of these drugs are given every hour or every two hours, and the treatment is continued until the passage of blood and mucus decreases and the evacuations become fæcal in character. Relief will generally be given after from six to eight doses, the patient feeling much more comfortable and experiencing much less pain and straining. In the first 24 hours the number of evacuations will not be lessened and at this time one can only judge of the success of the treatment by the feelings of the patient and by the character of the evacuations. In more chronic cases of dysentery rectal injections of boric acid and solutions of silver of nitrate are of service.

Post mortem more or less severe ulceration of the rectum and sigmoid flexure is usually found with thickening of the walls of the gut and enlargement of the mesenteric glands. Isolated patches of ulceration and inflammation of the rest of the colon often occur and the cæcum often suffers very severely. The small intestines are generally healthy, except that the lower part of the ileum has been inflamed in some cases. The amœba of dysentery has been searched for by Dr. Washbourn, but so far none has been discovered.

By far the largest number of our patients are suffering from typhoid fever of a very severe type. The chief strain seems to fall upon the circulatory apparatus and weak-running pulses of from 130 to 144 are not uncommon. The reason for this seems to be that the patients before contracting the disease have had excessively hard work to do, riding and marching for many hours every day, and this has no doubt weakened the resisting power of the heart in a disease which is known to severely attack the muscular structures throughout the body. Liberal quantities of champagne and brandy, with digitalis and strychnine, have to be given to tide the patient over his difficulties.

In all cases of doubtful diagnosis the Widal reaction is applied under the personal supervision of Dr. Washbourn. After dysentery sometimes chronic arthritis occurs with very little pain in the joint except on movement and with no swelling of the joint, but with a persistent temperature which has a suspicious resemblance to a typhoid fever chart. In one patient a doubt existed between the diagnosis of malaria and typhoid fever, so specimens of blood were examined by Dr. Washbourn for the plasmodium malariæ and a Widal's reaction was also tried. The plasmodium was found as masses of pigment in several of the red blood corpuscles and an immediate clumping of a typhoid culture pointed to the presence of typhoid fever. This double diagnosis has since been borne out by the subsequent progress of the patient. The Widal reaction is sometimes at fault. In one case of dysentery a strong and immediate reaction took place but typhoid fever was proved afterwards at the necropsy to be absent.

At present it is perhaps too early to condemn inoculation against typhoid fever. It certainly does not prevent a patient from contracting the disease, and it seems doubtful whether the inoculated person will show any greater immunity than the non-inoculated person. Slight attacks have occurred in both clases of patients and two patients in this hospital who were inoculated have succumbed to the disease. On *a priori* grounds one would hardly expect that a preventive serum treatment would be successful in a disease which after it has existed for something like three weeks cannot protect the patient from a relapse. Moreover, second attacks are by no means unknown and one of Dr. Richmond's patients had a most severe second attack of typhoid fever from which he died, so that a previous attack does not seem to protect either from the disease itself or to lessen its severity.

One cannot praise too highly the care and devotion to duty which has been shown by the nursing sisters, one and all, in their work in the hospital. It is, of course, in the treatment of typhoid fever that their assistance is of the utmost value, and many a convalescent soldier will owe his life to the skilful nursing of a trained sister. The arrangements for the treatment of cases of typhoid fever are most complete. Special huts are set apart for their reception and special sisters and special orderlies are appointed who never attend other patients. In addition to these arrangements a latrine for typhoid fever patients has been built in the midst of the huts occupied by those patients suffering from typhoid fever, where the evacuations are sterilised by disinfectants before they are destroyed, and where all soiled linen is soaked in

lysol for 24 hours before it is taken to the laundry to be washed.

Two interesting cases of relapse in typhoid fever have occurred. In the first case the patient's temperature rose about 10 or 11 days after his first attack and he had all the usual symptoms of a slight relapse, such as headache, malaise, pains in the limbs, slight abdominal distension, and enlargement of the spleen. The evening temperature remained up for seven days, with a normal temperature each morning after the first three days, during which time it rose to 102° F. On the eighth day the patient seemed quite well again; his temperature was normal and it remained so for five days. On the fourteenth day he was seized with pain in the abdomen and his temperature suddenly ran up to 105° without any preceding condition of collapse being noticed. His abdomen was rigid and did not move well with respiration. There was dulness of the lower part of the abdomen, especially on the right side, sickness began, and the pulse became more rapid and weaker. Dr. Washbourn, in connexion with Dr. Richmond, diagnosed a perforation of a typhoid ulcer, and laparotomy was performed by Mr. Raymond Johnson. A small perforation was soon discovered in the centre of a typhoid ulcer in the ileum of about the size of a shilling. The walls of the gut were too soft to allow of the ulcer being stitched up and so it was sewn into the wound and the peritoneum was washed out with boric acid lotion and the pelvis drained. The patient unfortunately sank a few hours after the operation. At the post-mortem examination it was found that this was the only ulcer present, although there were evidences of recent typhoid ulcers. It is thus clear that a single typhoid ulcer can give rise to a relapse, and that although such relapse may have a very short period of pyrexia it is of the utmo[illegible]nportance to treat such attacks with as much care as in the primary attack. In this instance the patient was kept on a strict diet of plain milk from the second day on which his temperature rose until his decease. In the second case a relapse occurred with all the usual symptoms and with enlargement of the spleen and with spots five weeks after the patient's temperature had been normal.

Deelfontein, May 14th.

ASSOCIATION OF BRITISH POSTAL MEDICAL OFFICERS.

ANNUAL DINNER.

THE annual dinner of the Association of British Postal Medical Officers was held under the chairmanship of the President, Dr. W. DOUGAN, on June 21st, at the Whitehall Rooms, Hôtel Métropole. The usual loyal toasts having been honoured, Sir JAMES CRICHTON BROWNE proposed "The Imperial Forces" in an eloquent speech and the toast was replied to by Sir JOSEPH FAYRER who said that he had endeavoured to record in the book which he had just written and published the history of his life's work and he had honestly done his best for those Services for which he was responding. For the rest of his life, which in the nature of things could not be very prolonged, he felt that he had the approbation of his *confrères* in the profession and of his brother officers in the Service, which he thought was the best reward a man could have. "The Houses of Parliament" was next proposed by Mr. EDMUND OWEN in a brilliant and witty speech, and was replied to by Mr. J. WALTON, M.P., who said that he had always entertained the idea that the House of Lords was a body of men independent of, and uninfluenced by, the voice of clamour, but that idea of his a short time ago received a shock when the peers surrendered on the vaccination question. Mr. EUGENE WASON, M.P., proposed, and Sir ROBERT HUNTER replied to, the toast of "The Postmaster-General, the Secretary, and other Executive Officers of the Post Office." "The Board of Education and other State Departments" was proposed by Dr. F. DE HAVILLAND HALL, and was responded to by Sir GEORGE KEKEWICH, Secretary to the Board of Education. Dr. J. F. W. TATHAM, Superintendent of Statistics to the Registrar-General's Office, also acknowledged the toast, and said that he wished to extend the usefulness of the statistics issued by his office. He had to thank the members of his own profession for the hearty support extended to him in the performance of his duties. The toast of "Preventive Medicine" was proposed by Dr. WOOD (Dulwich) and was replied to by Professor W. H. CORFIELD, who said that such was the excellence of the carrying out of the vaccination regulations in Germany that since 1874 no epidemic of small-pox had occurred throughout that empire, and as a result when a case of small-pox occurred in the extreme outlying parts adjacent to countries where the vaccination laws were carelessly enforced the first German medical officer seeing the case generally mistook it for chicken-pox. He himself could remember three hospitals in London where scarlet fever cases in times past were mixed up with the general patients. For his efforts to stop that he had received the severest possible censure from the chief physician of one of the hospitals concerned who was also medical officer of health; that alone showed how preventive medicine had advanced.—Dr. A. WHITELEGGE (Chief Factory Inspector), in giving the toast of "The General Medical Council," said that it was realised that the Council was endeavouring to make the profession more select by elimination of undesirable members and by increasing the stringency of the qualifying examinations.—Dr. J. G. GLOVER, in responding to the toast, said that it would be well for the medical profession if all gentlemen spoke of the General Medical Council with the generosity which characterised the remarks of Dr. Whitelegge. He (Dr. Glover) did not wish to save the Council from criticism for it was the better for it, but any fair student of its proceedings would conclude that with the limited powers it had it did the best it could. Nothing would do the Council more good than the encouragement of the profession. As a slight proof of the right of the Council to feel that it had done something for the profession he would refer to the question of infectious diseases. He himself had taken an active part in trying to increase the education of students in the matter. He was a member of the deputation sent to ask Mr. Ritchie to open the Metropolitan Asylums Board hospitals to students. It was possible for a man to be a most distinguished student and yet never see a case of small-pox and possibly measles. When the deputation went to Mr. Ritchie Sir Samuel Wilks related how Guy's Hospital had been asked to send a medical man to one of the important public schools, and the best man the hospital had was sent. There arose in the school a mysterious complaint which this gentleman had never seen before. He was so puzzled that he went to the oldest medical practitioner in the district and detailed the symptoms and was duly informed that he had to deal with an outbreak of measles. This defect in medical education the Council was trying to remedy. The unity of the profession would be best served and promoted by giving all encouragement to the General Medical Council, for it was the most representative body in the profession: it represented the medical schools in the United Kingdom, the Universities, the medical corporations, and the great body of the medical profession, though, of course, it must be admitted that direct representation was not as adequate as it might be. If they used the amount of direct representation which they had in the right way it would be increased, but they might so abuse it as to secure not extension but extinction. He (Dr. Glover) could say as one of the Direct Representatives that the other members of that Council representing the Crown and other interests paid great respect to the views of the Direct Representatives.—Dr. R. PARAMORE proposed "The Medical Press," which toast was suitably responded to.—The Rev. HENRY BELCHER proposed "The Association of the British Postal Medical Officers," and this having been replied to by the PRESIDENT, Dr. H. FITZGIBBON proposed "The Guests," which received due acknowledgment from Sir THOMAS ROE and Mr. P. J. FREYER.—A very cordial vote of thanks to the honorary general secretary, Dr. R. Ritchie Giddings, concluded the proceedings. The enjoyment of the evening was much enhanced by the excellent singing of Miss Lilian Corner and Mr. George Schneider and by a well-selected programme of music executed by the Imperial Orchestra.

THE NEW INFIRMARY AT NEWCASTLE.

THE foundation-stone of the Royal Victoria Infirmary was laid by the Prince of Wales on Wednesday, June 20th. The new building, which is to commemorate the Diamond Jubilee of Her Majesty the Queen, will occupy a site upon Castle Leazes and will take the place of the old infirmary which, by

its lack of adequate accommodation, has not for many years been able to minister to the wants of a greatly increased population. Briefly the story of the new building is as follows. In 1896 Mr. R. Lord was for the first time elected mayor of Newcastle and he initiated the movement to build a new infirmary to celebrate the Queen's Diamond Jubilee. He asked for £60,000, £1000 for each year the Queen would have reigned. This sum was raised more easily than it was expected it would be and Mr. Lord then asked for £40,000 more to rebuild the infirmary on its present site. While this money was being collected Mr. John Hall, a wealthy Newcastle merchant, offered to give £100,000 to build a new infirmary provided the site were changed and after great trouble and much delay ten acres of land were given by the corporation who own the soil and by the freemen who own the herbage on one of the sites selected by Mr. J. Hall on the Castle Leazes, at one time a part of the great Newcastle Town Moor. For the part which Mr. R. Lord has played in this gigantic undertaking he deserves the gratitude of the inhabitants of the counties of Northumberland and Durham. For 30 years at least the building of another infirmary in Newcastle has been talked of and from time to time efforts have been made to raise the requisite funds, but till Mr. Lord did it everyone thought the task impossible. Now at last a complete building will be erected. It will accommodate 400 patients and will probably cost, including the value of the site, £300,000. It will be one of the very finest hospitals in the kingdom.

The date chosen for the foundation-stone ceremony was particularly appropriate, inasmuch as June 20th is the anniversary of the Queen's accession to the throne. Never before have the streets of Newcastle been decorated as they were; bunting and other coloured decorations disguised the handsome stone buildings so that in many cases they could hardly be recognised, and the thoroughfares were thronged with such a crowd of visitors as has rarely if ever collected together in the stately old town. Fortunately the day, with the exception of a few slight showers, was fine and warm, so that everything contributed to make the laying of the foundation-stone a complete success. The Royal party arrived at the Central Station from York at 12.10 P.M. and were met by the Home Secretary, the Lord Lieutenant of Northumberland (Earl Grey), Lord Durham, the Mayor (Mr. R. Lord) and Mayoress, the Sheriffs, and the members of the corporation, together with many of the prominent citizens. An address, enclosed in a casket of ivory and gold, was presented to the Prince of Wales in the Assembly Room. His Royal Highness, who represented the Queen, having replied, a procession was formed and, escorted by a detachment of the Household troops, proceeded to a large covered stand capable of accommodating some thousands of spectators, where, in the presence of a huge crowd, the foundation stone was laid.

In reply to an address read by Professor G. H. PHILIPSON, M.D. Cantab., on behalf of the governors of the infirmary, the PRINCE OF WALES said: It gives me much pleasure to be here to-day, by the desire and on behalf of the Queen, my dear mother, to lay the foundation-stone of the beneficent institution which Her Majesty has directed shall bear her name in permanent commemoration of the wisdom of your corporation and freemen and of the generous charity of the inhabitants of this great city and the adjoining counties on the occasion of her Diamond Jubilee. The vast and varied industries which have grown up on the banks of the Tyne and maintain your population of resolute and prosperous workers are, unfortunately, in some instances carried on with a considerable, though happily diminishing, risk to life and health. It is therefore extremely gratifying to the Princess of Wales and myself to take part in the inauguration of a hospital so extensive and well equipped, where the best resources of medical science and of skilled and efficient nursing will be at all times available for the benefit of the suffering. We learn with satisfaction that a very generous contribution has been made by working men towards the endowment of the infirmary from which they will derive such benefits. I shall be happy to convey to the Queen your loyal and dutiful expressions of attachment and your good wishes, and I have to thank you for the cordial reception which you have given to the Princess of Wales and myself and to our daughter the Princess Victoria.

The Bishop of NEWCASTLE offered a special prayer and the MAYOR, on behalf of the architects, Mr. W. L. Newcombe, F.R.I.B.A., Newcastle, and Mr. Percy Adam, London, and of the contractor, Mr. A. Pringle, presented to His Royal Highness a golden trowel and a mallet. The Prince then declared the stone to be "well and truly laid."

The MAYORESS, on behalf of the governors of the Royal Victoria Infirmary, presented to the Princess of Wales a fan embellished with a view of the new building.

At a lunch which was afterwards served in the St. George's Drill Hall to some 900 guests the PRINCE OF WALES, in reply to the loyal toasts, said: In the name of the Princess and of our daughter and in my own name I must express our heartfelt thanks for the manner in which the Mayor has so kindly proposed this toast and for the cordial way in which you have received it to-day. ..... The Mayor having intimated a great wish that the Queen should lay the foundation stone of the great infirmary which is called after her name, she, being unable for various reasons to do so, deputed me to take her place. ..... I need hardly say how gladly I was able to take the opportunity of once more being among you, where we have always been so kindly received. Most sincerely do I hope that the building will meet all its requirements. The spot chosen seems to be a most excellent one, and I am glad to hear not only of the great munificence of a donor who, alas, has been taken from us, but that the working classes have shown the great interest that they take in their own welfare by subscribing considerable sums towards the institution. Everybody knows how celebrated Newcastle is for its great works and for its shipping. It is known all over the world. His Royal Highness then proposed the health of the Mayor and Corporation of Newcastle, to which he added the health of the Mayoress.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

ON July 5th the Fellows of the Royal College of Surgeons of England will be called upon to elect four members of the Council, and the occasion is remarkable, not for the number of vacancies, for in some years five vacancies have occurred, but for the large number of Fellows who have come forward as candidates. 12 Fellows will compete for the four seats, and so far as we are aware this number is absolutely unprecedented. There were, indeed, 13 candidates, but Mr. J. H. Morgan has retired, as Mr. J. A. Bloxam, his senior colleague at Charing-cross Hospital, is a candidate.

The electors will certainly experience some difficulty in deciding for whom they should vote. The motives which influence the voting are necessarily complex, but far above all others the influence of the medical school is felt, for as a rule Fellows support those candidates who come from their own medical school, and provincial voters support provincial candidates. There is much that is good in this feeling of loyalty, but we do not hesitate to point out that the power of electing to so important a body as the Council of the Royal College of Surgeons of England is a serious trust and it should be exercised not for the benefit of any individual, but for the good of medical education and of the medical profession at large. Those Fellows should be chosen who have shown themselves to have at heart the real advancement of surgery.

In considering the long list of candidates we find that three of them have already been members of the Council. Two of the retiring members, Mr. John Tweedy and Mr. Alfred Cooper, are offering themselves for re-election, and we imagine that all will agree that a retiring member of the Council who has served one term of office well is always justified in looking forward to being appointed for a second period. Mr. Tweedy was originally elected as representing the reform party in the College, and his conduct during the time he has already served has fully justified his appointment, for though he has shown himself at all times a zealous supporter of reform, he does not under-estimate the difficulties of the task. He has done good work on the Council and he would be certainly much missed by his colleagues should he not attain re-election. Mr. Alfred Cooper has also served one term and has proved himself a useful member of the Council; he will no doubt receive much support. Dr. Ward Cousins has not at present a seat on the Council though he has been twice elected a member. On each occasion he has replaced a member who through death has not finished his full term of

office; the result has been that though Dr. Cousins has had two terms of office he has only served four years.

Of the nine remaining candidates one, Mr. Jordan Lloyd, is a provincial Fellow, a well-known surgeon of Birmingham. At present there are only four provincial members of the Council, though there have been five, and if the electors consider that five members should be from the provinces they will elect either Dr. Ward Cousins or Mr. Jordan Lloyd. We are sure that either of them would be a useful addition to the Council.

The eight London candidates who have not yet been on the Council represent six medical schools, for Guy's and Middlesex each have two candidates, Mr. Clement Lucas and Mr. Golding-Bird being connected with the former and Mr. Pearce Gould and Mr. Bland-Sutton with the latter. Charing-cross is represented by Mr. J. A. Bloxam, St. Bartholomew's by Mr. W. J. Walsham, St. Thomas's by Mr. H. H. Clutton, and St. George's by Mr. W. H. Bennett.

As Sir Thomas Smith, who is retiring from the Council and does not intend to offer himself for re-election, is from St. Bartholomew's it is not unlikely that that medical school will be successful in replacing him by Mr. Walsham, although four members of the Council at present represent that hospital.

With regard to the other candidates we do not feel called upon to discriminate between so many able surgeons and we must leave to the electors themselves the onerous task of decision.

This year, as for several years past, the Fellows have been supplied with ballot papers so that they can vote by post, and there will be a still further falling off in the numbers of those who vote in person; but we would remind the electors that six Fellows must be present before the election can commence and would ask any London Fellows who can spare the time to attend at the College on Thursday next at 1.30 P.M.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6569 births and 3325 deaths were registered during the week ending June 23rd. The annual rate of mortality in these towns, which had been 16·8 and 18·0 per 1000 in the two preceding weeks, declined again to 14·9 last week. In London the death-rate was 13·3 per 1000, while it averaged 16·0 in the 32 provincial towns. The lowest death-rates in these towns were 8·0 in Birkenhead, 9·9 in Cardiff and in Nottingham, 10·0 in Norwich, and 10·2 in Portsmouth; the highest rates were 20·7 in Manchester, 21·2 in Liverpool and in Sunderland, 21·8 in Oldham, and 22·4 in Salford. The 3325 deaths in these towns included 366 which were referred to the principal zymotic diseases, against 386 and 427 in the two preceding weeks; of these 117 were referred to measles, 82 to whooping-cough, 64 to diarrhœa, 56 to diphtheria, 28 to scarlet fever, 18 to "fever" (principally enteric), and one to small-pox. No fatal case of any of these diseases occurred last week in Birkenhead; in the other towns they caused the lowest death-rates in Swansea, Nottingham, Halifax, Gateshead, and Newcastle; and the highest rates in Wolverhampton, Derby, Manchester, Oldham, Preston, and Sunderland. The greatest mortality from measles occurred in Plymouth, Derby, Manchester, Oldham, Huddersfield, and Sunderland; from whooping-cough in Oldham; and from diarrhœa in Wolverhampton, Preston, and Sunderland. The mortality from scarlet fever and from "fever" showed no marked excess in any of the 33 large towns. The 56 deaths from diphtheria included 21 in London, six in Leicester, six in Sheffield, and four in Leeds. One fatal case of small-pox was registered last week in Wolverhampton, but not one in any other of the 33 towns. The number of small-pox patients under treatment in the Metropolitan Asylums Hospitals, which had increased from three to 15 at the end of the five preceding weeks, had declined again to 13 on Saturday last, June 23rd; one new case was admitted during the week, against four, four, and eight in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1810, against 1754 and 1766 on the two preceding Saturdays. 219 new cases were admitted during the week, against 194, 203, and 210 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 268 and 257 in the two preceding weeks, further declined last week to 181, and were 28 below the corrected average. The causes of 44, or 1·3 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Nottingham, Salford, Bolton, and in 10 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Preston, Huddersfield, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·3 and 19·9 per 1000 in the two preceding weeks, declined again to 16·5 during the week ending June 23rd, but exceeded by 1·6 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 8·6 in Leith and 10·6 in Paisley to 17·0 in Edinburgh and 18·8 in Glasgow. The 510 deaths in these towns included 19 which were referred to diarrhœa, 18 to whooping-cough, 14 to measles, four to diphtheria, two to scarlet fever, two to "fever," and one to small-pox. In all 60 deaths resulted from these principal zymotic diseases, against 57 and 78 in the two preceding weeks. These 60 deaths were equal to an annual rate of 1·9 per 1000, which was 0·3 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had been seven and 22 in the two preceding weeks, declined again last week to 19, of which seven occurred in Edinburgh, five in Glasgow, two in Dundee, and two in Paisley. The deaths from whooping-cough, which had been 17 and 21 in the two preceding weeks, declined again to 18 last week, and included 16 in Glasgow. The fatal cases of measles, which had risen from 10 to 23 in the four preceding weeks, declined again last week to 14, of which 11 were registered in Glasgow and two in Edinburgh. The four deaths from diphtheria corresponded with the number in the preceding week, and included three in Glasgow, where the two fatal cases of scarlet fever and the death from small-pox were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 106 and 101 in the two preceding weeks, further declined last week to 87, but showed an excess of 13 over the number in the corresponding period of last year. The causes of 25, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·9, 23·1, and 23·8 per 1000 in the three preceding weeks, declined again to 17·9 during the week ending June 23rd. During the past four weeks the death-rate in the city has averaged 21·7 per 1000, the rate during the same period being 15·9 in London and 16·7 in Edinburgh. The 120 deaths belonging to Dublin registered during the week under notice were 40 below the number in the preceding week, and included four which were referred to the principal zymotic diseases, against three, 10, and six in the three preceding weeks; of these, two resulted from "fever," one from diphtheria, one from whooping-cough, and not one either from small-pox, measles, scarlet fever, or diarrhœa. These four deaths were equal to an annual rate of 0·6 per 1000, the zymotic death-rate during the same period being 1·5 in London and 2·1 in Edinburgh. The two deaths from "fever" corresponded with the number in the preceding week, while the mortality from diphtheria showed a slight decrease. The 120 deaths in Dublin last week included 23 of infants under one year of age and 28 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a decline from the numbers recorded in the preceding week. One inquest case and one death from violence were registered; and 47, or more than a third, of the deaths occurred in public institutions. The causes of eight, or nearly 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified: — Staff-Surgeons: James M'C. Martin, D.S.O., and W. E. Home to the *Centurion;* and H. P. Shuttleworth to the *Boscawen* for the *Minotaur*. Surgeons: Richard C.

Munday to the *Nelson*; S. Roach to the *Centurion*; William Walker, John O'Hea, Leonard S. Whitwan, Herbert, Denny, Alfred J. Hewett, and Gerald M. Eastment, to the *Duke of Wellington*, additional for disposal; Robert W. G. Stewart, John St. John, Murphy Henry J. Rogers, Alex. C. Remirck, Walter P. Dyer, and Thomas H. Vickers, all to the *Vivid*, additional for disposal; Robert R. Fasson, Arthur F. Fraser, and Ralph B. Ainsworth, to the *Pembroke*, additional for disposal; John R. Muir, Arthur F. Frank, and Richard R. Horley, to the *Wildfire*, additional for disposal; A. W. Campbell to the *Lizard*; A. Gaskell and J. D. S. Milln to the *Centurion*: and J. P. H. Greenhalgh to the *Prince George*.

INDIA AND THE INDIAN MEDICAL SERVICES.

The following promotions are approved:—To be Colonel:—Lieutenant-Colonel Charles Henry Joubert, Bengal Establishment. Majors to be Lieutenant-Colonels: *Bengal Establishment:* Charles Pardey Lukis, Robert Richard Harvey Whitwell, Lawrence Augustine Waddell, Dhanjibhai Barjorji Spencer, James Clarke, Cooverjee Cawasjee Vaid, Philip Durrell Pank, Thomas Richard Mulroney, and Thomas Rankin Macdonald. *Madras Establishment:* Rustam Hormasji Cama, Winthrop Benjamin Browning, C.I.E., Crosdaaile Miller Thompson, Cubitt Sindall Rundle and James William Evans. *Bombay Establishment:* Henry Peers Dimmock and Charles Bradley Maitland. Captains to be Majors: *Bengal Establishment:* Daniel Grove Marshall, David Macbeth Moir, Harry Frederick Whitchurch, V.C., James Reid Roberts, Frederick William Gee, Kanta Prasad, Patrick Wilkins O'Gorman, William Henry Gray, and George Thomas Mould. *Madras Establishment:* Allan Ewen Grant and Frank Charles Pereira. *Bombay Establishment:* James Graham Hojel, Henry Charles Leffler Arnim, and George Sloane Thomson. The transfer of the undermentioned officer to the half-pay list is also approved: Captain John William Wolfe, Bengal Establishment. The retirement from the service of the undermentioned officers is also notified:—*Bengal Establishment:* Lieutenant-Colonel Charles James Hislop Warden, Lieutenant-Colonel Richard Nugent Stoker, and Lieutenant-Colonel Thomas Rankin Macdonald. *Bombay Establishment:* Lieutenant-Colonel Atmaram Sadashiva Graudin Jayakar.

MILITIA INFANTRY.

Ernest Madge, late Surgeon-Lieutenant, Militia Medical Staff Corps, to be Captain.

VOLUNTEER CORPS.

Artillery: (1st Cornwall) Duke of Cornwall's (Western Division, Royal Garrison Artillery): Surgeon-Major W. Mason to be Surgeon-Lieutenant-Colonel; Surgeon-Captain W. K. Bullmore to be Surgeon-Major. Submarine Miners: The Clyde Division: Surgeon-Lieutenant J. Rowan to be Surgeon-Captain. *Rifle:* 8th Volunteer Battalion the Royal Scots (Lothian Regiment): George Alexander Dickson to be Surgeon-Lieutenant. 1st Volunteer Battalion the Royal Warwickshire Regiment: Surgeon-Major E. L. Freer to be Surgeon-Lieutenant-Colonel and to remain Supernumerary. 3rd (Dumfries) Volunteer Battalion the King's Own Scottish Borderers: Surgeon-Lieutenant G. D. Logan resigns his commission. 4th Volunteer Battalion the East Surrey Regiment: Surgeon-Major E. J. Lawless to be Surgeon-Lieutenant-Colonel and to remain Supernumerary. 1st Nottinghamshire (Robin Hood): James Black Roberts to be Surgeon-Lieutenant.

Memorandum.—Consequent upon the division of the 1st Volunteer Battalion the Lincolnshire Regiment into two Volunteer Battalions, designated respectively the 1st and 3rd Volunteer Battalions the Lincolnshire Regiment, Her Majesty has been graciously pleased to approve of the following with effect from June 20th, 1900, and of the officers so transferred being considered to have received in the new battalion commissions of the same rank and date as in the consolidated one, viz.:—1st Volunteer Battalion the Lincolnshire Regiment: Surgeon-Major F. J. Walker and Surgeon-Lieutenant J. Bruce.

TRANSVAAL WAR NOTES.

Lieutenant Carlyon, R.A.M.C., Civil Surgeon Bruce, and Civil Surgeon M. P. Cooke have left England for South Africa. Major Bond, R.A.M.C., is on his way to England wounded in the *Armenian*. Civil Surgeon Stamford is returning to England in the *Bavarian*. Lieutenant Buist, R.A.M.C., Major A. B. Cottell, Lieutenant H. G. Martin, Lieutenant Scott, Civil Surgeon Callum, and Civil Surgeon Smith have arrived in England. The following officers were discharged from hospital to duty for the week which ended June 10th: Civil Surgeons Smallman and Civil Surgeon Hunter. Major A. Wright, R.A.M.C., and Surgeon-Lieutenant-Colonel Lawless, 4th Battalion East Surrey Regiment, were discharged from hospital to duty for the week ending June 17th.

On June 19th Princess Henry of Battenberg visited the Syracusa Convalescent Home for Wounded Soldiers at Torquay. This institution, which at present contains 28 soldiers, several of whom are Canadians, was founded by Mr. and Mrs. Mallock. Mr. J. Quick described each case and Her Royal Highness had a cheering word to say to each of the men.

Mrs. Skey Muir, the honorary secretary of the Royal Army Medical Corps South African Fund, notifies all those who have been interested in the work of this Fund that the offices, 77, George-street, Portman-square, W., will be given up early in July and that no parcels can be received after the 7th prox. Gifts in money may, however, still be sent to the bankers, Messrs. Holt and Co., 3, Whitehall-place. Should it be found desirable to resume the work in the autumn due notice will be inserted in the daily press.

Invalids from South Africa, consisting of 23 officers and 200 men, have arrived in Plymouth this week and have been admitted into the Station Hospital, Devonport. In addition to the camp hospital for 50 beds which has been established at Fort Staddon the hospital at Tregantle Fort has been increased to 50 beds. Both these hospitals will be further increased should the occasion arise.

The s.s. *Cheshire* and *Pembroke Castle* arrived at Southamyton on June 19th and June 22nd respectively. The former brought 392 and the latter 334 sick and wounded from South Africa who were admitted to the Royal Victoria Hospital. We hear that in future convalescent patients will be sent on from the troopships to Portsmouth and that only men really requiring medical treatment will in future be admitted to the wards of the hospital.

TRANSVAAL WAR CASUALTIES.

Surgeon-Lieutenant-Colonel James Stevenson died at Cape Town on June 19th.

Mr. Benton Norman Maclean, medical officer attached to the Imperial Light Horse, is reported to have died from ptomaine poisoning at Ladysmith.

Captain J. H. Campbell, R.A.M.C., was severely wounded during the operations in Natal on Feb. 24th.

The following are reported dangerously ill:—At Bloemfontein: Surgeon-Lieutenant-Colonel W. W. Lake, Militia Medical Staff Corps. At Kimberley: Civil Surgeon W. H. Steele. Civil Surgeon W. B. Bennett, attached No. 1 Stationary Hospital, Natal. At Kroonstad, June 16th: Civil Surgeons R. W. Jameson and A. Robertson.

Lord Roberts telegraphs that the following sick officers are reported to be at Heilbron: Major Greig, R.A.M.C., and Civil Surgeon Ash, enteric fever; doing well.

THE CRISIS IN CHINA.

A *Times* telegram through Reuter's agency, dated Calcutta, June 26th, states that a wing of the 7th Bengal Regiment, together with the 43rd Field Hospital, embarked on June 25th on board the *Nerbudda*.

In a subsequent telegram, dated Simla, June 26th, the *Times* says: Major Cree, R.A.M.C., will proceed on hospital duty with the force. Lieutenant Douglas and Captain Walton of the Indian Medical Service have been placed in charge of the x rays apparatus, of which there is only one complete set available here.

The following Indian medical officers will accompany the regiments proceeding to China: Lieutenant-Colonel Bookey (principal officer), Lieutenant-Colonel Esmonde-White, Majors Mould and Whitchurch, V.C., and Captains Kenrick, Walton, and Price. Those proceeding with the hospitals are: Lieutenant-Colonel Waddell, Majors Burton, Fooks, Thomson, Marshall, and White, Captains Jenny, Carr, Moorhead, Harriss, and Hamilton, Lieutenants Fenton, McCay, Megaw, G. Stewart, Willmore, Meakin, Gidney, and C. Stewart.

ROYAL VISIT TO NETLEY HOSPITAL.

On June 21st H.R.H. the Princess Louise, Duchess of Argyll, visited the Royal Victoria Hospital with Mrs. Eliot Yorke with whom she was staying at Hamble Cliff. Arriving at the hospital at 2.45 P.M. Her Royal Highness was met by Colonel Charlton, R.A.M.C., accompanied by his secretary (Major Treherne, R.A.M.C.), and by Professor A. E. Wright, and was conducted through the wards of both the medical and surgical divisions of the hospital. In the

former the cases were explained to the Princess by Lieutenant-Colonel W. E. Webb, R.A.M.C., and in the surgical division by Major W. Dick, R.A.M.C., acting Professor of Surgery, and by Major Birt, R.A.M.C., the latter being the officer in charge of the surgical division. The Princess remained in the hospital for rather more than two hours.

ARMY MEDICAL SCHOOL, NETLEY.

Under orders from the Director-General of the Army Medical Service a special examination was held at the Army Medical School on June 20th and 21st to examine the surgeons-on-probation who had been nominated for the Royal Army Medical Corps. The following gentlemen were recommended for commissions as Lieutenants:—

1. P. Henderson.
2. J. P. Murphy.
3. A. R. Greenwood.
4. F. H. Hardy.
5. W. M. H. Spiller.
6. D. W. K. Moody.
7. A. D. Jameson.
8. W. Bennett.
9. B. B. Burke.
10. W. B. Fry.
11. C. R. L. Ronayne.
12. G. Baillie.
13. L. L. G. Thorpe.
14. J. B. Hall.
15. W. S. Crosthwait.
16. P. G. Douglass
17. R. F. Ellery.

DEATHS IN THE SERVICES.

Lieutenant-Colonel George Frederick Bevan, I.M.S., recently, who qualified as L.R.C.S. and L.R.C.P. Irel. in 1870 and 1871 respectively, met with a serious carriage accident at Bangalore in April last. He was recovering from its effects when pneumonia set in which rapidly proved fatal.

Lieutenant Charles William McG. Orpen, I.M.S., at Quetta, recently, from pneumonia. Lieutenant Orpen, who had only recently entered the service, graduated as M.B., B.Ch., and A.B.O. Dub. in 1897.

Correspondence.

"Audi alteram partem."

THE POSITION OF THE GENERAL MEDICAL COUNCIL WITH RESPECT TO THE MIDWIVES BILL.

To the Editors of THE LANCET.

SIRS,—As President of the General Medical Council I have been authorised and requested to state, should certain amendments to the Midwives Bill now under consideration in the House of Commons be placed on the notice-paper, that the Council at its last meeting carefully considered the bearing of the most important of these amendments and passed the following resolution:—

That the Council request the President to represent to the Lord President of the Privy Council that the amendment of Clause 2 (2) of the Midwives Bill by the omission of the words "or shall habitually and for gain attend women in childbirth" would so completely destroy its efficacy as a measure of protection for lying-in women of the poorer classes, that the Council could no longer approve of the Bill passing into law; and that accordingly they deem it unnecessary at the present time to express an opinion on the other amendments suggested.

As I understand that an amendment for the omission of the words referred to has been placed on the notice-paper I have to request that you will favour me by publishing this letter so that the Medical Council's position on this matter may be known.

I am, Sirs, yours faithfully,

June 26th, 1900. WM. TURNER.

THE RIGHT OF THE LICENTIATE OF THE SOCIETY OF APOTHECARIES OF LONDON TO STYLE HIMSELF "PHYSICIAN AND SURGEON."

To the Editors of THE LANCET.

SIRS,—Subjoined is a copy of a resolution passed by the Court of Assistants of this Society on June 19th. Having regard to the great importance of the resolution to the Licentiates of the Society I shall be much obliged if you will allow it to be published in your next issue.

I am, Sirs, your faithfully,

June 26th, 1900. JAMES R. UPTON.

The resolution passed by the General Medical Council at its recent session deciding not to employ the funds of the Council in defraying the expenses of a test case to determine whether the L.S.A. (1886) is or is not entitled to call himself Physician and Surgeon having been read,

Resolved, that in view of the opinions expressed by eminent counsel in favour of the Society's contention, and this court considering that the decision of the General Medical Council ought not to operate to the prejudice of the Licentiates of the Society, hereby authorises all Licentiates of the Society qualified under the Medical Act, 1886, to call themselves Physician and Surgeon and undertakes to defend them at the sole cost of the Society from the legal consequences of their adopting those titles.

THE DAVIES-COLLEY MEMORIAL FUND.

To the Editors of THE LANCET.

SIRS,—The irreparable loss which our hospital and medical school have sustained through the death of Mr. Davies-Colley while still with us in active work has awakened a general desire to perpetuate his memory. It is felt that there are many who will be eager to testify in some lasting form to Mr. Davies-Colley's great ability, unvarying uprightness, and daily devotion to duty. To this end at a meeting of the medical staff it was decided to invite subscriptions. The form which the memorial shall take will be determined at a meeting of the subscribers to be held at a later date. Subscriptions may be sent to Dr. T. G. Stevens at the address as below.

We are, Sirs, yours very truly,

CHARTERS J. SYMONDS, Treasurer.
THOS. G. STEVENS, Hon. Secretary.

8, St. Thomas's-street, London Bridge, S.E., June 28th, 1900.

LYMPHATIC LEUKÆMIA.

To the Editors of THE LANCET.

SIRS,—I have read with some interest the account of the case of lymphatic leukæmia published in THE LANCET of June 16th by Dr. Murrell. While agreeing with the author as to the importance of recording new and successful treatment in this disease, I should submit that the diagnosis is not so clear as was assumed. The diagnosis of lymphatic leukæmia is based upon three cardinal symptoms: (1) progressive hyperplasia of the lymphatic glands; (2) marked increase in the numbers of white blood corpuscles in the circulation; and (3) abnormally high percentage of lymphocytes. It is true that Muir and others have published cases in which the hyperplasia of the lymphatic glands was absent, but I am aware of no record of a case in which the latter two symptoms were also absent. In Dr. Murrell's case there is no mention made of the condition of the lymphatic glands, the number of white corpuscles was never above the normal; in fact, in the first and third counts there was a considerable leucopenia, and as regards the percentage a clear differentiation was not made between lymphocytes and hyaline corpuscles. I would further suggest that the condition described as "small cells having a single pale nucleus ..... surrounded by a narrow zone of fine granules staining very deeply with methylene blue" is such as is not infrequently seen when blood is deeply stained with methylene blue. Ehrlich[1] in describing the lymphocyte says: "The protoplasm shows with methylene blue and similar stains inequalities in the intensity of staining which must be regarded, not [as Ehrlich first thought] as the expression of a granulation, but as a net-like structure." It would be advisable that the indicated points should be cleared up before such a valuable case is put on record.

I am, Sirs, yours faithfully,

J. CHARLTON BRISCOE.

King's College Hospital, June 20th, 1900.

"ACCIDENTAL VACCINATION OF A WOMAN BY HER CHILD."

To the Editors of THE LANCET.

SIRS,—A case similar to that reported by Mr. Henchley in THE LANCET of June 23rd (p. 1846) occurred to me last year. A lady came to stay in this neighbourhood bringing her infant with her and in a few days she sent for me. She was suffering from pyrexia and from diffused redness of the face and much swelling which seemed to have its centre near the nose. The case seemed so obviously to be one of facial erysipelas that I notified it as such. Within two or three days a copious serous discharge from her nostrils began and continued for a week. As these symptoms slowly subsided the unusual course of the case led me to inquire further, and it came out that the infant had been vaccinated shortly before coming

[1] Die Anæmia, p. 46.

here, and by this time a small sore was discovered at the left side of the tip of the nose, just within the nares. The discharge ceased and the swelling decreased and eventually only a small scar was left. In this instance it appeared likely that the infection was conveyed from the infant's arm to the mother's nose through the medium of a pocket-handkerchief.—I am, Sirs, yours faithfully,

Blackheath, June 23rd, 1900. WALTER KIDD, M.D. Lond.

"HORSE AMBULANCES."

To the Editors of THE LANCET.

SIRS,—Perhaps the ancient and loyal borough of Wigan can lay claim to having one of the most complete systems of ambulances of any similar town in the kingdom. When I tell you that there are stationed in the town and district no fewer than 24 horse ambulances and 12 hand-wheel ambulances it will be at once evident that both Wigan and the district are doing their share of the work indicated in THE LANCET. But this has been going on for 20 years. The ambulance movement has all along been voiced through the annual report of the Royal Albert Edward Infirmary and through the local press, and there has not been lacking that spirit of magnanimity and generous kindness on the part of friends of this hospital to provide what was needed to establish this excellent hospital corps of which we are justly proud. The medical men in the district have done their share in giving lectures on "first-aid and ambulance work" in the various works, so that within a circle with a radius of nine miles from this hospital you will find men who have profited by those lectures and have possessed themselves of certificates or medals granted for proficiency by the St. John Ambulance Association.

I am, Sirs, yours faithfully,

WILLIAM TABERNER,

General Superintendent and Secretary, Royal Albert
June 26th, 1900. Edward Infirmary, Wigan.

MIDWIVES' REGISTRATION.

To the Editors of THE LANCET.

SIRS,—The protest published in THE LANCET of June 16th from the Beckenham and Penge Medical Society regarding the conduct of the Cannon-street Hotel meeting contained in a letter of sympathy to Dr. Glover would not require an answer did it not contain the statement that the delegates of that society went there "prepared to submit some very carefully considered alterations in the Midwives Bill which they hoped might render it a useful measure and one which would safeguard the public and be acceptable to the general practitioner." Of these "carefully considered alterations" we heard nothing either at the preliminary committee meetings or at the meeting itself. And how can this statement be made consistent with this society's delegates (including Mr. Sturges) having composed and signed the following, which is an extract from a letter which accompanied the invitation to the meeting?

> It is the opinion of the large majority of medical men, and particularly of general practitioners, who see most and know most of the class of work the Midwives Bill is intended to legislate for, that it is a measure likely to effect incalculable harm. Even if it provided, as it does not, for restricting to natural cases of labour only the legalised attendance of midwives, the harm would not be guarded against, for a natural case of labour requires complete scientific knowledge to diagnose and may become urgent and dangerous at any time between its commencement and completion. Since the study of midwifery has been changed, chiefly owing to the labours of the late Sir James Simpson and the Edinburgh School, from a despised art to an honoured science, the saving of life and suffering has been immense (as statistics will show) and the genus Mrs. Gamp, so powerfully exposed by Charles Dickens, has been disappearing by the ordinary process of evolution. That being so, the evil which we all recognise to exist seemed to be gradually curing itself; but the effects of this legislation, we fear, will be to revive it in a more dangerous form than ever existed before. The Medical Acts, which were drafted in the interests of the public, wisely ordained that medical men who are licensed to practise in any one branch of medicine or surgery (including midwifery) must show a thorough knowledge in all. Going absolutely against this principle the Midwives Bill will give a State-guaranteed qualification to women who can at most possess the little knowledge that is dangerous, which will deceive the public into thinking that in employing a midwife they are employing a properly qualified person to whom they are justified in entrusting their lives. We feel very strongly that this Bill has not been properly considered or the effect it will have sufficiently weighed; and although we wish all who follow the calling of nurse to the sick could be properly trained and even certificated by law we are convinced that no measure which provides for the attendance of lying-in women without proper medical supervision can fail to be productive of a largely increased death-rate among women and infants and also do much to encourage criminal practices.

This is the rational and consistent position which we still hold and the one from which they have apparently been washed back by the dogmatic ground-swell of medico-political orthodoxy.

I am, Sirs, yours faithfully,

Sydenham, June 17th, 1900. F. LORIMER HART.

HEALTH AND SANITARY CONDITION OF ABERDEENSHIRE: BRAEMAR SPECIAL DISTRICT.

To the Editors of THE LANCET.

SIRS,—In the issue of THE LANCET of June 9th, 1900, page 1682, under the heading of "Health and Sanitary Condition of Aberdeenshire," at the end of the paragraph it is stated that "scavenging has improved in all the districts except Aboyne, Torphins, and Braemar, '*where nothing has as yet been done.*'" This statement is incorrect as regards the Braemar district, where a scavenger has been employed for the last three years and paid a regular salary during that time. I have, therefore, to ask you to contradict the latter part of the paragraph in so far as Braemar district is concerned.

I am, Sirs, yours faithfully,

WM. MICHIE.

Clerk to Braemar Special District.
Tullochcoy, Crathie, June 23rd, 1900.

THE RAILWAY MEDICAL OFFICERS' UNION.

To the Editors of THE LANCET.

SIRS,—It will be a very great convenience and will considerably aid organisation amongst railway medical officers if you will allow me to ask those who previously communicated with me, as well as those who have not, if they will let me know as soon as possible whether they could attend a meeting at Ipswich during the session of the annual meeting of the British Medical Association, with a view of instituting a union for the protection and promotion of the interests of railway medical officers.

I find that the medical officers of some railway companies are already organised, having had associations for some years. If they will attend the proposed meeting their experience will be of use, not only in assisting the medical officers of other companies to form associations on their respective lines, but also in forming the national union.

There is nothing revolutionary intended in the proposed union. The objects are (1) to promote unity and good fellowship; (2) to compare the rates of payment of the different staffs; (3) to consider whether there should be a separate payment for minor surgical injuries as well as to consider the special fees for fractures, dislocations, &c.; (4) to consider the question of gratuitous or paid ambulance lectures; (5) to consider how we can protect each other from those who are seeking the appointments which we hold; and (6) finally to consider any other means which may be proposed from any member or staff likely to be for our mutual benefit.

If I hear from a sufficient number of medical officers I will make arrangements for a meeting at Ipswich and shall be glad to know what day and hour during the annual meeting will be most convenient for each writer. I not only wish to hear from those who have made arrangements to go to the annual meeting of the British Medical Association, but those who could make it convenient to run there specially for this meeting but have not the time at their disposal to remain for any other meeting. Our meeting will not be restricted to members of the British Medical Association. I shall be glad to hear from those unable to attend a meeting at Ipswich whether they are favourable to the union and will give it cordial support, in all cases stating what company they are attached to and any details connected with their appointment that may be of interest and utility to their colleagues. All communications will be regarded as confidential, facts only being made use of, not the names of the authors.

I am, Sirs, yours faithfully,

G. H. BROADBENT,

Medical Officer G.N. and G.C.Ry. Cos.
8, Ardwick-green, Manchester, June 25th, 1900.

CHELTINE FOODS.

To the Editors of THE LANCET.

SIRS,—Referring to your remarks on Cheltine Foods in THE LANCET of June 16th, when treating of the exhibits at the Medical, Surgical, and Hygienic Exhibition, we beg to state that the wording on the tins of diabetic food "Cannot turn into sugar" was a clerical error. Correction was made on our pamphlets two months ago but was unfortunately omitted on the diabetic tins. This has now been corrected, and in future all tins containing diabetic food issued by this company will have written on them "Will not form diabetic sugar."—We are, Sirs, yours faithfully,

WORTHS FOODS SYNDICATE, LTD.

Cheltine Works, Cheltenham, June 18th, 1900.

"CORONERS' INQUESTS ON PERSONS DYING UNDER ANÆSTHETICS."

To the Editors of THE LANCET.

SIRS,—On reading your excellent leading article in THE LANCET of June 23rd, p. 1811, with regard to the questions propounded by Dr. Danford Thomas to be put, I presume, to medical witnesses at future inquests on deaths from anæsthetics, I could not help wondering whether the well-known coroner can possibly have any practical knowledge of the difficulties of complying with the suggestions which his questions would imply. A large number of the cases in which a general practitioner is called to give an anæsthetic are cases more or less of emergency, perhaps in some country village miles away from any professional assistance, cases in which there would be no time to make the thorough examination of the patient and the surroundings as suggested, or even if that were possible cases in which even unfavourable conditions might have to be ignored more or less. By all means let us have scientific inquiry with regard to anæsthetics, but I cannot help thinking that the general practitioner is being somewhat hampered by all the minutiæ of detail expected of him, which will make many men almost shrink from giving an anæsthetic. For instance, one of the questions suggested by Dr. Thomas is the experience of the anæsthetist. True, the more experience an anæsthetist has had the better for the patient and everybody. But it is not possible for all to have the same experience and many a young general practitioner may be called upon as a bounden duty to give an anæsthetic whether he has had experience or not. If the questions propounded by Dr. Thomas are to be put on every occasion of a fatality and the jury are to give their verdict according to the answers received, I for one, although I have had a fairly large experience of anæsthetics—i.e., ether and chloroform—hope I may never have to give any more if I am to run the risk of having my professional credit upset by a jury who are certainly not a competent tribunal on those matters.

I am, Sirs, yours faithfully,

June 26th, 1900. M.B., M.R.C.S.

THE NATIONALISATION OF TRINITY COLLEGE, DUBLIN.

To the Editors of THE LANCET.

SIRS,—Although I am unable to discern that the columns of a medical journal are the proper arena for the discussion of the Irish Catholic University question I feel bound to contest your conclusion, as set forth in an annotation in THE LANCET of June 23rd, p. 1815, that the proposal to nationalise Trinity College is "as useless as it is impracticable." I hold, on the contrary, that the nationalisation of the College, which I understand to be the same thing as the complete de-sectarianising of it, would be most useful because it would remove for ever the only complaint which Irish Catholics can justly make against the Dublin University system. Trinity College is, indeed, national already but for one thing. Its education in arts, science, medicine, law, and engineering, and its degrees in these faculties, are as freely open, with all the honours of the higher grades, to Roman Catholics as to the students of any other religion. No questions are asked or any exclusion practised towards them, and many Roman Catholics who have passed through Trinity with honour have testified to that fact, and no grievance can be truthfully averred respecting the educational treatment of students of that or any other Church. There is, however, that within the University and its College which unfortunately affords grounds for the complaint that Roman Catholics are liable to be exclusively dealt with therein. The atmosphere is very strongly redolent of Protestantism, and the governing body, the Professors and Fellows and officials, are almost universally Irish Churchmen, and it would be no more reasonable to expect Irish Churchmen to feel comfortable in their studies at Maynooth than to expect Roman Catholics to feel comfortable at Trinity.

That the Protestant atmosphere is so thick in Trinity is due not to any desire on the part of the Protestants to boycott the Roman Catholics but to the refusal of the Catholic priesthood to allow their co-religionists to bear a hand in any form of Irish education over which they have not, practically, despotic control. They have pursued towards Trinity the same policy which they pursued towards the Queen's Colleges, using every effort to make them failures and then screeching that the institutions should be superseded because they *are* failures. No one in Ireland, I imagine, entertains any hope that the Catholic hierarchy will abandon this position until they must and the parade of imaginary grievances will no doubt continue, but if the nation recognises that the education of the people ought not to be chopped up for division amongst a number of sects and compels the Government to turn a deaf ear to the clamour of the Irish priests and to force Trinity to accept liberalisation and desectarianism the Irish University question will be solved as the nation desires. It may be true, just at present, that "no statesman of any party would attempt to interfere with Trinity College," but when we had a strong hand at the Ministerial helm instead of the time-serving Government which now rules the attempt was made and nearly succeeded and there is no doubt that the liberal voice of the British electors would now support any Government which would have the courage to ignore the assumed indignation of the Irish priests and proceed to eradicate all traces of sectarianism from the University of Dublin. To effect this latter purpose it would be essential to transfer in its entirety the Divinity school of Trinity College to the outside custody of the Church of Ireland with a grant to that Church equivalent to that now made to the sectarian education at Maynooth and elsewhere. Without this the Roman Catholics will always have a reasonable grievance and the priests a good cry for a separate Catholic university, and I see no insuperable difficulty in doing it whenever the nation has a Government whose regard for justice and for the interest of the people will restrain it from trafficking with parties for votes.

I am, Sirs, yours faithfully,

June 26th, 1900. A.M., M.D. DUB. UNIVERSITY.

PLAGUE IN AUSTRALIA.

(FROM A SPECIAL CORRESPONDENT.)

THE returns of plague in Sydney for the week ending May 12th are as follows: remaining at the beginning of the week, 99; admitted, 23; discharged, 26; died, 10; remaining at the end of the week, 86. The totals up to the end of the week are as follows: cases, 216; deaths, 73; discharges, 57. "Contacts," 1242; "contacts" remaining, 153; cases among "contacts," seven. The population of Sydney should, perhaps, have been mentioned at an earlier date; it is about 456,000. Its composition is a matter much misunderstood in some quarters, in which it seems to be supposed to resemble that of South African towns. The truth is far otherwise. Australia is a white man's country, and it will not be the fault of the present generation if it does not remain so. The people are white, European or of European descent on both sides, and in preponderating proportion British. The only coloured people present in number of importance, in relation to vital statistics for instance, are the Chinese; but only 3465 were enumerated at the census of 1891, since when restrictive laws have prevented their immigration, hence nearly all the plague patients have been whites which might be inferred also from the gross death-rate. Only five coloured people have suffered; all of them were Chinese. Three have died, while two are likely to die.

Another point on which something may be said usefully is as to the completeness of the returns which have been given

from week to week. No doubt is entertained in any quarter that they are complete. That the first case discovered was the first case in reality is most probably the truth. It was certainly—the word is here used deliberately—not preceded by any important number of minor or of ambulant cases; one or two such there may have been; more there surely cannot have been. And if early in the epidemic it should be guessed that there may have been some oversight of declared or bubonic cases they diminished very quickly at all events; but the general feeling is that there never can have been more than (say) half a dozen at the outside. This is the opinion of all in a position to judge—of the resident staffs at the hospitals, for example, and of the staffs of the department of public health. As regards the latter, no doubts are entertained by it; it has the confidence of the profession which knows that its members will be rationally dealt with. A good many cases have been reported rather late, and even occasionally after death under medical care; but no one who has been puzzled by early symptoms fears that he will be rudely brought to book under the law, or that he will be asked publicly to explain his delay in reporting. On the other hand, all have learned that anything like wilful concealment or gross delay in reporting (in the case of other infectious diseases dealt with under the same law) is dealt with strictly. But the distant critic unacquainted with local conditions will be inclined to argue that wilful concealment of cases has occurred. He will refer to the early cases—if, indeed, cases of plague they were—in Calcutta. But the truth is that no evidence which would enable a reader to form an opinion was adduced regarding them;[1] a bare statement that the bacillus was observed comprised it. What, exactly, it was that was seen was not described; and whatever the bacteriological competency of an observer may be that, in a case where the possibilities of mistake are many, is not enough. From other quarters the evidence of precedent cases of ambulant plague—those, namely, in which there is recognised glandular swelling—is that practitioners remembered meeting with such cases which "must have been" plague, only after plague had become epidemic. Now, at first, attention was often drawn in Sydney to instances of glandular swelling, but they were almost always easily traced to one or other of the recognised causes and in reality were reported for protection; hardly ever had the patient any symptom of general illness, but the swelling was chronic, or at least of long standing. In one or two cases the cause of the swelling could not be made out, but then the most careful consideration and bacteriological examinations failed to afford the slightest support to a diagnosis of plague. In short, with as thorough a knowledge of plague as could be got from epidemiological and clinical study of accounts of the disease and its outbreaks, acquired long before the disease actually appeared here, nothing at all has been observed to support the notion that those causes of incompleteness in the epidemiological accounts which have existed or have been assumed in other cases have occurred here. The great importance of this matter in relation to certain etiological views is a good reason for writing upon it at some length.

There is little of interest to note except the diminished number of new cases for the week already shown above. The Millard house on having its floor taken up revealed a dry sandy soil and nothing else. The newly admitted cases show the same degree of virulence in the infection as at first on the average. Inoculation has recommenced; arrangements have been made for inoculating the inhabitants of the infected area and those employed there in preference to others, but comparatively little interest is shown by the public. On the first two days a few more and a few less than 100 respectively presented themselves.

May 15th.

[1] Papers relating to the Outbreak of Bubonic Plague in India to March, 1897.

THE DURHAM MEDICAL GRADUATES' ASSOCIATION.—The annual meeting of this association, followed by a dinner, is held alternately in London and Newcastle-on-Tyne. This year the turn of Newcastle came, very opportunely on the eve of the visit of the Prince of Wales. Many Durham graduates practising in London were present. The association is prosperous and betrays a warm affection for its *alma mater*. The dinner was held at the Grand Hotel, Barras Bridge, and was ably presided over by Dr. W. C. Beatley.

THE UNIVERSAL EXHIBITION AT PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

Opening of the International Congress Season.—Graphology.—Agriculture and Health.—Grocers and Health.—Women's Work and Health.—The Housing of the Poor.

THE season for international congresses has now fairly begun. There were only three such congresses in the month of May, but 23 are taking place during the course of this month. The congress which in the month of May attracted the most general attention was that of graphology; a fact which is not surprising when we remember how experts in handwriting quarrelled over the celebrated Dreyfus *bordereau*. I am not aware, however, that anything was said about the graphology of medical prescriptions though this was certainly a subject on which a very interesting paper might have been written, beginning with some account of the mystic invocation to Jupiter which heads a prescription and concluding with some sarcastic allusions to the art of illegibility. Among the congresses that have already been held this month was that of the friendly and benefit societies called Le Congrès de la Mutualité. When the medical profession is better organised it should contrive to have a voice at such gatherings so that the other side of the questions treated may be brought forward. As it was we were treated to panegyrics on the advantages of thrift and on the benefit and growth of organisations the principal object of which it is to provide for a rainy day. Of course all this is excellent so far as it goes, but to accumulate vast reserve funds at other people's expense is not quite so estimable a performance. That the working classes and the small trading classes should be praised for such foresight and economy as they have displayed is quite right and proper, but at the same time it should be known that a part of these funds is not the result of economy and saving but the direct profit obtained by sweating members of the medical profession. It does not suffice to say this outside; it should be repeated within such congresses, so that it might be heard and understood by those who are responsible for the widespread grievances that afflict a large section of the medical profession in most countries. Another important congress was that of the grocers. I have not much to say about this meeting beyond mentioning the fact that there was an imposing British delegation of over 100 members. Considering how at scientific international congresses, such as that of hygiene, Great Britain is often very feebly represented, I must confess to a feeling of discouragement when I found that the grocers manage these things much better than the medical profession. But the grocers had also some things to say that affect public health. They were loud and bitter in their complaints against the truck system and against trusts which not only ruined legitimate trade but which, by abolishing competition, placed the public at the mercy of the monopolists. Such monopolists could more easily foist unwholesome articles on to the public, or sell things at exorbitant prices. The delegates, though they represented the master grocers, very generally agreed that the hours of labour for their shop assistants were too long and that they should be reduced. In this respect England was mentioned as a model nation where there is not only complete rest on Sundays but generally a half holiday in the middle of the week. It would be worth while holding such congresses if for no other purpose than to spread this custom to other nations among whom the exaggerated duration of the day's work for shop assistants has a very detrimental effect on public health.

M. Casimir-Perier, formerly President of the French Republic, presided over the Congress on Agricultural Education. He eloquently urged that every effort should be made to render education in agriculture at once attractive and easy, for it was most necessary to check the continual migration of the rural populations to the great towns. Though most of the speakers supported this view from the economical standpoint its importance as a question of national health and national defence was also admitted. It is from country districts that the best soldiers are recruited, and this for the simple reason that rural populations are healthier than town populations. In the name of the French Government M. Jean Dupuy, Minister of Agriculture, wished

the delegates welcome, so that the congress had a good set-off. Mr. Sutton represented the British Royal Agricultural Society, and there were influential delegations from the United States and most of the European nations. Here, then, was another opportunity, while keeping well within the programme of the congress, of propagating principles and projects of reform which would not only promote the interests of agriculture but also benefit the public health. The principal resolution adopted by the congress was in favour of teaching in universities and high schools those sciences which bear upon agriculture, such as chemistry, zoology, botany, geology, vegetable pathology, bacteriology, &c. Needless to point out, though the agriculturist would study bacteriology in view of preserving vegetable life and the lives of cattle, &c., he would not fail to realise that in many respects the same principles apply to the preservation of human life. The brotherhood of the sciences is an undeniable fact and a most beneficent fact, and hence sanitary reformers are well within their scope of action when they wish every success to the scientific agriculturist. Besides, on agriculture depends our food-supply and therefore it was but natural that several medical men should attend this congress. Dr. Cathélineau, for instance, read an interesting paper on the bacteriology of milk, insisting also that butter often contained the bacillus of tuberculosis and that therefore milk should be always sterilised. As the dairy industry depends on fermentation it should be conducted under conditions of the most perfect asepsis. There was also a good deal said about the cultivation of the vine and the necessity of legislation to prevent the adulteration of wine. The sale of cheap pure wine best contributed to prevent the evils of alcoholism, therefore a resolution was carried in favour of abolishing all local taxation (*octrois*) on wine. When natural wines became scarce and dear they were replaced by manufactured alcohols, with the result that there was invariably a great increase in drunkenness, crime, and insanity. The agriculturists in wine-growing countries had to be taught not only how to contend against the diseases that devastated the vineyards, but also how to employ such precautions in the making, bottling, &c., of wine that it would be able to travel and to keep without being strengthened by adding the more or less poisonous alcohols of commerce. Thus in many ways the Congress on Agricultural Education treated questions that might appropriately find a place in a congress of hygiene.

Then there has been an immense gathering of women—women politicians, women of science, and women authors and artists; but far more numerous than all these were the women engaged in works of charity and philanthropy. It was the Congrès des Œuvres et Institutions Féminines. I am not aware that there is a good equivalent in the English language for the word "œuvres." It means work, but work for a particular purpose or mission, and all charitable organisations come under this denomination. Now there are so many works of this description that from the very first the congress was hopelessly blocked by the reports brought by the delegates who individually were all naturally anxious to prove how very worthy of sympathy was their own particular mission. Those reports brought by the foreign delegates took up three-quarters of the sittings. Altogether there were more than 200 of such reports. In many cases only summaries could be read and it was rarely possible to discuss the points raised. Therefore the congress became terribly monotonous, yet these documents have a literary and historical value, but they are better suited for publication in a volume than for a congress. There was, of course, a great deal said about the care of children and about institutions affecting the same. A somewhat sharp discussion arose when Madame Dussaud urged that *crèches* should not be converted into institutions offering a premium on idleness. Therefore before admitting the children an inquiry should be made as to the position of the parents, but Mesdames Bazaine, Kauffmann, and Louise Dehor retorted that a little child or infant should not be made to suffer on account of the idleness or vice of its parents, and Mademoiselle Bonnevial protested that the object of day nurseries, &c., was not to punish bad parents but to save unfortunate children. The congress adopted various resolutions to increase the financial and other help given to poor mothers and to render it illegal for any woman to work during the first month following upon her confinement. Of course, the old arguments against the Contagious Diseases Act were brought forward again, but M. Trarieux and M. Bérenger, Senators, urged that such regulations were necessary for the preservation of public health. Madame Pognon, profiting by this division in opinion, attacked virtuous women for their want of sympathy with their fallen sisters, who were generally driven to a deplorable life not through any inherent vice of their own, but by the force of economical circumstances. It was not contempt but sympathy and a true understanding of the situation which alone would remedy the evil. In respect to this want of understanding of the true position of women, Mademoiselle Selma Riza attempted to show that Mahommedan women held a better legal position than Christian women. Mahomed was a great advocate of women's rights and also a great sanitary reformer. Consequently married women controlled their own property independently of their husbands, and if divorced retained the care of their children. On the other hand, as there is and can be no prostitution among Mahommedan women, Contagious Diseases Acts when employed in Mahommedan countries only affected the Christian populations. Unfortunately the instructions given by Mahomed that young women should be carefully educated had to a large extent been neglected, and consequently many Mussulman women had fallen into a condition of apathy and ignorance and led lives that might be considered as a sort of slavery. This was their own fault and contrary to the text and spirit of their laws and religion. A delegate from Alsace, Madame de Schlumberger, in regard to the question of morality thought that a mother should above all strive to remain the friend, companion, and confidante of her son during the critical period of adolescence. A mother should not fear from a mistaken feeling of modesty to speak of certain subjects, for it is on these very subjects that young men most need experienced advice. The congress adopted a resolution to this effect. In dealing with economic questions, which of course materially affect public health, for with extreme poverty sanitation becomes almost impossible, the congress adopted a motion in favour of what might be called a Woman's Homestead Act. Already in France it is illegal to seize for debts the bed and the implements of work, such, for instance, as a sewing-machine. These enactments should be enlarged so that homes cannot be so readily broken up. Another resolution adopted proposed to abolish all work for wages under the age of 16. Such is the nature of a few out of the enormous number of questions brought before this congress. They will suffice to show how the subjects treated often affected, directly or indirectly, the causes that bear upon public health.

The Congrès des Habitations à Bon Marché (artisans' dwellings and the housing of the poor) has also met this month and was presided over by M. Jules Siegfried, Senator and formerly Minister of Commerce. Mr. David Waterlow attended on behalf of his father, Sir Sydney Waterlow, who as chairman of the Housing of the Working Classes Committee in the British House of Commons was one of the honorary presidents of the congress, together with Mr. Geoffrey Drage, M.P. M. Siegfried in opening the congress expressed his sense of shame at the fact that so large a proportion of the peasantry still ignored the most elementary comforts and decencies of home-life. While in large towns there were block buildings where the rate of mortality attained the appalling figure of 80 deaths per 1000 per annum, yet the death-rate of the town as a whole might be even lower than 20 per 1000. To remedy this disgraceful loss of life sanitary reformers, architects, engineers, and financiers should come together and devise healthy dwellings where the rent charge should not exceed from 3 to 4 per cent. of the capital invested. Actually the rents paid amount to from 5 to 60 per cent. on the capital cost of the buildings. But if we were to reduce the profits of capitalists from 60 per cent. to 3 or 4 per cent. on moral grounds we must also make the tenants realise on moral grounds that they should not squander in unnecessary things what they should reserve for the essentials of existence. M. Siegfried concluded by quoting Jules Simon, who said: "Without home there is no family; without family there is no morality; without morality there are no men; and without men there can be no nation." M. George Picot, Permanent Secretary of the Academy of Moral and Political Sciences, read a lengthy paper on Artisans' Dwellings. He is an economist of the old school and fears State intervention. Nevertheless, he did admit that it might be useful and without peril to remove such legal obstacles as exist preventing the investment of capital which is locked up. In every other respect he argued in favour of existing conditions and it was difficult to see

where reform was to find a footing. Capital refused to be "moralised" and preferred high dividends. But if an outside influence should set a good example then investors might become reconciled to smaller profits in the face of such competition. M. Cheysson suggested that conflicting interests might be reconciled by a system of profit-sharing between proprietors and their tenants. The latter would then be less likely to injure the houses in which they dwelt. But this suggestion met with only scant support. M. Weber thought that the State was in any case quite justified in building homes for the aged and infirm. Reports were read describing what had been done in England—the Peabody buildings, the County Council common lodging-houses, &c. Lengthy arguments were held as to whether State or municipal intervention tended to paralyse private enterprise. M. Hector Denis, the well-known Belgian economist, was strongly in favour of municipal tenements and lodging-houses and was supported by many members of the congress, including several directors of private enterprises. The congress adopted a motion effecting a compromise and declaring that as circumstances differed greatly in the various countries the question of State intervention should be reserved for future congresses. But in any case the State must actively interfere to enforce all necessary sanitary regulations, and the congress determined to elect a permanent international committee to collect information.

Paris, June 24th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Cawnpore Plague Riots.—Improved Plague Mortality.—Birthday Honours.—The Anti-rabic Institute.

THE Local Government resolution recently issued explains the origin and course of the Cawnpore plague riots. There seems to have been a general fear of plague in the city and an ignorance of and uncertainty about the plague regulations. The compulsory removal to hospital and segregation of two cases seem to have inflamed the people and while they were gathering for a general meeting a false rumour was started about a boy being forcibly removed to the hospital to be burnt alive. The mob made for the hospital, murdered the head constable and five other men, and set fire to the huts of the hospital and segregation camp. A large assembly of the roughest elements afterwards took place on the parade-ground. As many of the men were armed with big sticks and were prepared for a disturbance the magistrate thought it wise to have them disarmed. Fortunately he arrived with the 5th Bengal Cavalry and had the ground cleared, but there was a great deal of stone-throwing. Thinking the disturbance was over the cavalry returned to barracks. The mob, however, broke out again and had it not been for the presence of the Volunteer Light Horse, who were compelled to fire on the crowd, there is no knowing what massacres might have taken place. The next day was more peaceful and conferences took place about the plague regulations. The inquiry showed that the people had not been sufficiently informed about the plague regulations, that the police were utterly useless, being apathetic and ignorant and without any information as to the state of feeling among the populace, and that the leading natives failed to lend any assistance and apparently gave covert support to the agitators.

I am pleased to be able to record a great reduction in the plague mortality throughout India. There were only 975 deaths in the whole of India last week. The Bengal Presidency had 388 deaths and the Bombay Presidency 519.

The following medical practitioners have come in for Birthday Honours:—Colonel Campbell, I.M.S., of Shillong; Captain C. H. James, I.M.S., of Jullunder; Miss Charlotte Adams, L.R.C.P. Edin., of Jodhpur; Miss Susan Campbell of Ajmere; Mrs. H. Smith of Jullunder; and Major Stevenson, I.M.S., of Allahabad, the two first-mentioned getting the Kaisar-i-Hind gold medal and the others the silver medal. I have not heard of any honours having yet been given to the plague medical officers who were appointed by the Secretary of State.

An Anti-rabic Institute for India is at last an accomplished fact. After numerous delays Government have stepped in and practically settled the difficulties. The Indian Chiefs' Victoria Jubilee Bacteriological Institute came to nought and the scheme for a Pasteur Institute has hung fire for years. The Royal Army Medical Corps, having an officer in Major D. Semple who had studied in Paris and Lille, determined to utilise his experiences, and the annual expense for sending soldiers to Paris was diverted for the new institute. The central committee of the proposed Pasteur Institute saw their opportunity and took over its control. With a capital of Rs. 70,000 and a yearly grant of Rs. 19,500 the expenses of the new institute ought to be fairly well met. The public may congratulate themselves that at last means are provided whereby European and native patients alike can be offered the best available treatment for the terrible disease of rabies.

May 24th.

The Famine, the Cholera, and the Coming Monsoon.—The Decline in the Plague Epidemic.

THE famine shows no signs of abatement and the total number of people under famine relief for the whole of India has now reached 5,700,000. The Central Provinces chiefly are affected. In the Bombay Presidency cholera has been decimating the labourers on the relief works. At Hadmatia there is a camp of 25,000 people and the disease is of a most virulent type. The scare has almost emptied the camp.

Intimately associated in interest with the present famine are the prospects of the coming monsoon. Unfortunately the forecasts are not favourable. The weather at Mauritius is reported as being more like that of April than of May, at the Seychelles the wind is unsteady, and the south-east trade winds between the two islands are unusually light, with less rain and sea than usual. These reports seem to indicate considerable delay in the advance of the south-east trade winds towards the Equator, and the current seems to be determined more than usual towards the Zanzibar coast.

The plague mortality continues to decline throughout India, only 746 deaths being reported for last week. From Bunder Abbas it is announced that plague has appeared at Kishm and that 18 cases have occurred since April 30th. The Australian papers report plague as prevailing at Sydney, Fremantle, Adelaide, Melbourne, and Brisbane. Rats teeming with plague have been found in Melbourne. There is also a death reported from Durban, the victim being an East Indian.

The trial of inoculation has been fairly extensive but in Bombay city, notwithstanding that the number of people inoculated has reached nearly 200,000, little impression seems to have been produced on the current outbreak. The prophylactic has been used this year in Karachi, Sholapur, Surat, and Aden.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Tramps and their Children.

AT a meeting of the Chorlton Board of Guardians, held on June 22nd, the subject of the best mode of dealing with tramps and their children came up for discussion. A communication from the Coventry Board of Guardians was read, asking them to support the following resolution: "That the Local Government Board be asked to give the guardians permission to detain tramps for a period of seven days, and that while such tramps are performing the legal task of work their children should receive such elementary education as could be given by the proper officials." When one considers the results that follow the more systematic methods of the elementary schools, the effect of a week's tuition even by the most earnest and skilful teacher would not be very visible on such waifs and strays and would be dissipated by the time the next stopping-place was reached. Dr. J. M. Rhodes who has had much experience in, and thought much on, such subjects considered that there should be power to detain such children for at least six months and that the guardians should have authority to detain and educate them just as they had for children not under proper guardianship. This would no doubt be good for the majority of the children, but some would object to the interference with the parental relationship and its duties. Among the habitual tramps, however, the

former is but lightly regarded and the latter is not regarded at all, and the best thing that can happen to the children is to get free from their parents. But some of the homes for "waifs and strays" would be in many ways preferable to workhouse schools.

Anatomical Society of Great Britain.

The summer meetings of the Anatomical Society of Great Britain have been held this year in the Medical School, Owens College. At the close of the meeting on June 22nd Professor G. D. Thane of University College, London, proposed a vote of thanks to the Council of Owens College for their kindness in receiving and entertaining the members of the society. It was seconded by Professor A. M. Paterson of Liverpool and carried. In the afternoon Professor A. H. Young gave a garden party and in the evening the annual dinner took place. Mention should be made of the admirable arrangements for the meetings, the credit for which is due to Dr. Peter Thompson, the honorary local secretary for the Manchester visit.

Manchester Medical Staff Corps.

The Manchester Medical Staff Corps has by the services of the 85 men serving in South Africa earned the approval of the Director-General of the Army Medical Department. It appears that he inspected the companies at Aldershot and pointed out that there was so much sickness among the troops that for a long time more men of the department would be wanted, and he asked for additional volunteers. About 30 men have already volunteered for service from the Manchester companies, and they are being sent to Aldershot with all speed. It is expected that they will sail for South Africa on June 30th. It is pleasant to know that Surgeon-Captain Coates, to whom the Manchester corps owes so much, has been raised to the rank of surgeon-major.

Bar Parlours and Tuberculosis.

Dr. J. Wheatley, medical officer of health of Blackburn, in his annual report just issued, states that no places, excluding the workrooms of some trades, are more favourable to the spread of tuberculosis than bar parlours and other frequented rooms of public-houses. This is not to be wondered at when one considers the filthy habits as to expectoration too common among those who frequent these places and the neglect of cleanliness that often obtain with the people having the charge of the lower-class drinking-places. He urges most scrupulous cleanliness in the management of these places. He also says that the birth-rate has been steadily declining since 1872, and was last year the lowest on record.

The late Professor Thomas Jones.

A special meeting of the medical and surgical staff was held at the Manchester Infirmary on June 26th. A resolution was unanimously passed expressing their deep sense of the loss which the institution has sustained and their sorrow for the death of their late colleague Professor Thomas Jones. A further resolution was passed asking the chairman of the board, Mr. Hardie, to forward it to Mrs. Jones with expression of their sympathy with her in the irreparable loss which she has sustained. It need scarcely be said that the news of Professor Jones's death was received by the medical profession in Manchester and by a wide circle unconnected with the profession with the deepest regret. Strongly urged to accept the superintendence of the Welsh Hospital Professor Jones went to South Africa under a sense of duty which he felt unable to put aside. His departure was cheered by the good wishes of colleagues, friends, and students, and he went ready, if need be, to lay down his life for his country. The sacrifice has been made and in his grave at Springfontein rests all that is mortal of a brave man, one of the heroes of peace.

Hospital Organisation.

The board of management of the Manchester Royal Infirmary at their meeting on June 25th considered a communication from the Manchester and Salford Hospital Inquiry Association. The association thought that there was a considerable abuse of hospital charity from (1) the insufficiency of the means taken to investigate the circumstances of the patients; (2) the necessity under present conditions of showing a large return of work done, as estimated by the number of patients and consultations; (3) the tendency to accept trivial cases as suitable for continuous treatment; and (4) the custom at some special hospitals of treating cases outside the proper scope of their work. The association also recommended a conference of representatives from all the hospitals of Manchester and Salford with authority to create a united hospital board or to deal specifically with the causes of hospital abuse and to discuss the acceptance of contributions from patients. The board replied to the effect that they took reasonable and sufficient means to prevent the abuse of the charity; that there had not appeared to be any necessity for the infirmary to show a larger return of work than was actually done, a statement of which is given with the annual report; that the acceptance of all cases for treatment absolutely rested with the medical staff; and that the fourth question did not affect the infirmary. The creation of a united hospital board was not, in the opinion of the board, desirable, as they believed that each hospital committee was best capable of managing in its own way the affairs of the institution over which it had control.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Epidemic of Typhoid Fever in Belfast.

THE epidemic of typhoid fever in Belfast is still with us and in the week ending June 21st 50 cases of the disease were notified. Two views as to the cause of this epidemic are put forward. The Public Health Committee say that the cause is the bad water-supply, and as evidence they point to the statements made by witnesses of the Water Commissioners (when they were promoting a Bill last year before a Parliamentary committee) as to the pollution of their catchment area at Stoneyford. To prevent this risk in the future the Commissioners obtained Parliamentary powers to buy compulsorily all farms the drainage of which might find its way into the Stoneyford reservoir. Now the Public Health Committee allege that this has never been acted upon and it is hinted that before the present outbreak there was a risk of typhoid excreta again reaching this reservoir. Other links in the chain of evidence that the present epidemic is water-borne are the facts that the places specially affected are on the direct supply from the Stoneyford reservoir and that, as stated in the public press, the water in the houses affected even to the naked eye is dirty and deposits on a handkerchief, as it filters through, a dark residue. But up to the present no scientific bacteriological evidence has been given as to the condition of the water in the affected houses. This form of laboratory examination takes time, but the Public Health Committee, alive to its great value, are not neglecting to have it done and Belfast is awaiting the result. The second view is that the disease is due to the soil being permeated with disease germs due to the defective drainage of so many of the jerry-built houses of Belfast; and, in truth, details brought before a meeting of the Public Health Committee on June 21st show an alarming state of affairs. It would appear that between April 25th and June 16th the drains of 819 houses in which typhoid fever occurred in the north division of the city had been tested. Of these, 431, or 52·6 per cent., were found in good order, and 383, or 47·4 per cent., were defective. In the south division of the city 731 houses in which typhoid fever occurred had been tested, and of these 342, or 46·8 per cent., were found to be in good order, and 389, or 53·2 per cent., were defective. Over 50 per cent. of the drains of houses where typhoid fever had not occurred had been found defective, and probably 50 per cent. of the drains of old houses are more or less defective, while the majority of the present cases of typhoid fever have occurred in a district where the houses are new and built on virgin soil. Now I think that these facts (and they were brought before the Public Health Committee at their meeting on June 21st) prove that sufficient attention in the past has not been paid to house sanitation in Belfast and that had a proper and effective supervision been exercised in the construction and arrangement of the drains there would have been far less typhoid fever. A single case of typhoid fever coming into a district where there is defective drainage will spread the disease, and with such admittedly defective sanitation is it any wonder that the city of Belfast is never free from the disease? The Public Health Committee may blame the water-supply and say that it is the cause of the epidemic, but the Water Commissioners may in

truth retort, If so, why is the epidemic not more general and may it not be more likely at the present time due to the acknowledged defective sanitary arrangements of so many houses in Belfast? Everyone knows that in Belfast typhoid fever is never absent—it seems to be endemic; but at times there is, as at present, an alarming recrudescence of the disease assuming the type of an epidemic. No theory of the prevalence of the disease will be sufficient which does not explain these facts. I think it is probable that there are two causes—the water and the defective drainage; and that neither the one nor the other is the *causa causans*, but that both take their share in giving rise to the disease. Unquestionably the present water-supply of Belfast is not good and that from the Stoneyford district is most suspicious. The Water Commissioners should push on rapidly with their new scheme which will bring a splendid supply of pure water from the Mourne mountains and in the meantime they should exercise their powers to buy out the farms in the neighbourhood of the catchment area at Stoneyford; while, on the other hand, the Public Health Committee must insist on the drainage of the houses of Belfast being made right and it is to be hoped that no more jerry-building (the great curse of Belfast in the past) will be permitted. All that is wanted is strictly to enforce the rules against such practices which already exist.

Municipal Honour to a Medical Man.

The Limerick Corporation on June 16th conferred the freedom of the city on Mr. Thomas Myles, M.D. Dub., F.R.C.S. Irel. He is a native of Limerick and was recently elected President of the Royal College of Surgeons in Ireland.

June 26th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Disinfection of Wells.

AT the meeting of the Academy of Medicine held on June 19th M. Delorme, the well-known military surgeon, gave a description of the methods employed by him for disinfecting the wells in the camp at Chalons. Steam pressure disinfection after the method of Neisser does not give the results claimed for it by that observer. According to him steam generated in a powerful generator under a pressure of five atmospheres should raise the temperature of the water to 95° C. and finally to 110° C. This process, Neisser considers, effects an absolute disinfection with great rapidity. It is, however, expensive, the average cost per well being 37 francs. Also it is not easy to carry out, for M. Delorme, employing a large Geneste-Herscher stove as a generator, could not raise the temperature of the water in the well more than from 20° to 30°. M. Delorme then had recourse to permanganate of potassium which in doses of from five to 10 centigrammes per litre destroys all organic matters as well as all living organisms. He estimated the quantity of water in the well and added the proper proportion of permanganate. A brown oxide of manganese is formed which is quite harmless and which can be precipitated by adding to the water a little powdered charcoal and fine sand previously sterilised in a stove. One part of charcoal should be used to three parts of sand. At the end of three-quarters of an hour thorough disinfection has taken place, the charcoal has been deposited, and the water is quite clear. A bacteriological examination carried out during a period of three months showed that the water after undergoing this process contained only an insignificant quantity of microbes—namely, 1026 per cubic centimetre—while before treatment the water contained 72,306 per cubic centimetre and had a most offensive smell. In another well, the water of which before treatment was very offensive and contained in addition 112,160 microbes per cubic centimetre, after treatment it contained only 150 per cubic centimetre. The alleged difficulty in the use of permanganate—namely, that it leaves in the water an amount of potassium which is dangerous to health, is groundless, for examination of the water after treatment shows only very slight traces of potassium. Besides, it is perfectly easy to use permanganate of lime instead of the potassium salt. M. Delorme concluded by saying that in his opinion this method was the best for the disinfection of wells, for it is easy, quick, and cheap, the cost being only about one franc per well.

A Forerunner of Pasteur.

A monument has just been unveiled at Teste de Buch to a humble French medical man who passed all his life from 1779 to 1851 in this little hamlet, but who was perhaps one of the most intelligent medical men of the century. He was the initiator of the Pasteur theory, and there is to-day but little to add to the brochure of 100 pages which he published in 1836 under the title of "Reflections sur les Virus." His name was Jean Hameau and he lived all his life devoted to the interests of his patients. He was almost the first to put vaccination into practice in the year 1801, and in 1812 he read a paper before the Society of Medicine at Bordeaux on the Transmission of Glanders (*Morve*) from a Dog to Man. In 1818 he discovered the existence of pellagra, a disease then completely unknown in France. It was not until 1847 that his work upon viruses appeared in the *Revue Médicale* and he died quite unknown. In 1884 M. Solles made the work definitely known to the inhabitants of Bordeaux; and in 1895 a second edition was brought out by the son of the author, with a preface by Professor Grancher in which full credit was given to the humble practitioner of Teste. Jean Hameau was veritably the first to formulate the nowadays triumphant doctrine of living and transmissible germs and of contagious viruses which reproduce themselves when sown in a favourable soil. He made many attempts to discover the germs of vaccinia and variola, of measles, and of scarlet fever, but without success; nevertheless he held firmly to his conviction. If only he had possessed the laboratory accommodation and means of investigation available at the present day the microbe theory of disease would have been established 50 years earlier than it was. To-day he is honoured by a bronze statue erected on the initiative of the medical men of the department where he worked, and toward the expenses of which the whole profession subscribed. The monument was unveiled on May 27th and orations were delivered, but it is impossible to avoid a feeling of sadness at the reflection that as in the analogous cases of Duchenne and Morvan, who were pathologists of the first order but who never rose from the ranks of humble practitioners, the spectacle is so often seen in France of men with brains and intellects far above the average who live unknown and whose work meets with no response simply because they do not belong to the official ranks of the world of medicine.

The Feeding of Tuberculous Patients.

At a recent meeting of the Hospitals Medical Society M. Letulle, physician to the Boucicaut Hospital, described the *régime* upon which he put his tuberculous patients. Every patient has six meals per diem. At 6 A.M. when they awake they have tea and milk. At 8 A.M. they have soup and meat powder. At 11 A.M. they have a breakfast composed of three different dishes. At 3 P.M. a lunch of cold meat is given. At 5.30 P.M. they have dinner, which consists of soup and three dishes, and at bedtime—namely, at about 8.30 P.M.—they have a glass of milk and some rusks. In addition some patients have extras, such as cream, eggs, and raw meat. Under this *régime*, together with rest, most tuberculous patients, whether in the first, second, or third stage of their disease, put on weight in a wonderful manner. Unhappily, however, after some weeks the weight remains stationary and occasionally decreases little by little to the amount at which it was when the patient was admitted. As a rule men derive more benefit than women from their stay in hospital, for in the case of the latter the recurrence of menstruation nearly always brings about a loss in weight. The practical conclusion to be drawn from these facts is that tuberculous patients should be transferred to the country as soon as their weight remains stationary.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Reciprocity of Medical Practice.

THE intimation of the Privy Council to the General Medical Council that Part II. of the Medical Act of 1886 will be applied to Italy has been received with the greatest satisfaction by British practitioners resident here. This willingness on the part of Great Britain to grant the Italians the reciprocity of medical practice which the latter profess

to desire will, it is hoped, prevent the passing of the restrictive measures lately agitated for by certain Italian practitioners—measures which, had they become law, would have deprived foreign practitioners of all the privileges which they now enjoy. While it is far from certain that these privileges may not yet be withdrawn, the action of the Privy Council has, at all events, removed a powerful weapon from the hands of those here who founded their demand for the exclusion of British practitioners upon the alleged illiberality of the English law regulating foreign practice in Great Britain. It is even thought by some that the result may be the establishment of that equal and full reciprocity of medical practice between the two countries on which such stress was laid in the discussion of this question during the last session of the General Medical Council. When the recent dissolution of the Italian Parliament took place a Bill had been prepared proposing to limit still further than at present the rights of the foreign practitioner. Under the existing law any foreign practitioner may attend all foreigners indiscriminately. Under the proposed law only foreigners belonging to a country which grants reciprocity of medical practice to Italians could be attended by other than an Italian practitioner. Moreover, only foreign practitioners holding diplomas from such a country would have been permitted to practise in Italy. A double restriction would thus have been imposed by the new law. To British practitioners it would have probably amounted to prohibition, since the Italians do not admit that the British law in its present state permits them to practise in Great Britain; and even if it were not for this reason prohibitory the measure would have had the effect of cutting off the American practice which forms under existing conditions so large a proportion of the British practitioner's work. Although the proposed measure did not find favour among the better class of the profession here it would probably have passed in the form indicated, since its champion, Dr. Santini (who, by the way, has been re-elected by his constituency), is a man of considerable Parliamentary influence, and because the majority of the Chamber of Deputies would have been indifferent in the matter. Now, however, that such a clear pronouncement has been made by the Privy Council of the intentions of the British Government, the hope at least seems justified that a proposal so much at variance with the repeatedly expressed desire of the Italians themselves for reciprocity will not be revived, and that in any future legislation for regulating foreign practice in Italy the claims of British medical men to fair and liberal treatment will be fully recognised.

Award of the Balbi-Valier Prize.

The biennial prize of 3000 lire (nearly £120) which was founded by Balbi-Valier has been awarded by the Venetian Institute of Sciences to Professor Grassi of Rome for his work on the mosquito and its relation to malaria.

Medical Legislators.

Amongst those lately elevated to the rank of Senator of the Kingdom appear the well-known names of Professor Maragliano of Genoa and Professor Golgi of Pavia. Professor Sanarelli of Bologna has also been elected one of the Deputies in the new Parliament.

The Malaria Problem.

Dr. L. Sambon and Dr. Low, the two medical men entrusted by the British Government with the perilous task of testing the possibility of guarding against malarial infection in the Roman Campagna, have at length found a favourable place for their purpose. After rejecting various other localities as for one reason or another unsuitable, they have selected a spot about two miles distant from Ostia, between Castel Porziana and Castel Fusano, and within five minutes' walk of the latter place. The site of their hut is on the edge of a "stagno," or swamp, forming part of the royal hunting demesne of Castle Fusano, and left undrained in order to preserve the wild boar, water fowl, &c., which frequent it. The hut will stand close to a canal containing a luxuriant growth of algæ and other aquatic plants and within a stone's throw of a clump of pine trees, which forms the outskirts of the Castel Fusano pine forest. The few dwellings near are inhabited by peasants who constantly suffer from malaria and are infested by mosquitoes of the anopheles variety. Situated thus in the heart of the swamps surrounding the mouth of a large river, among the haunts of innumerable mosquitoes of the malarial variety and in a locality notorious as one of the most deadly of the fever-stricken centres of the Roman Campagna, this dread and unhealthy spot appears to offer ideal conditions for the carrying out of the interesting but dangerous experiment now about to be begun. The two daring investigators hope to have everything in readiness early in July; in the meanwhile their time is profitably occupied in studying the animal and insect life of the Campagna, collecting and examining frogs, lizards, bats, spiders, mosquitoes, and the like. They have already made some interesting observations, as, for example, that although the larvæ of anopheles are at this season apparently very few, the adult mosquitoes are collected in the houses in great numbers, being especially numerous near byres and stables. The King has graciously given his consent to the erection of the hut in the royal preserves, and the municipality of Rome are doing everything in their power to help the enterprise.

June 22nd.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Montreal General Hospital.

AT the annual corporation meeting of the Montreal General Hospital, held in the latter part of the month of May, Dr. F. G. Finley, the secretary, presented the annual report. It showed that the income of the year from the ordinary sources was $76,421.72 and the ordinary expenditure $81,570.75, an excess over receipts of $14,149.63. As compared with the previous year the expenditure shows an increase of $1082.24, while the income shows a decrease of $1605.23. The total number of indoor patients treated to a conclusion during the year was 2824, being 94 more than in the previous year. Of these 189 remained over from the previous year and 2810 were admitted during the current year. 176 remained in the hospital at the end of this hospital year. 2629 were discharged, 195 having died in hospital, thus making the total of 2824. In regard to the 195 deaths 106 of them occurred within the first three days of their admission, a result in great measure due to severe accidents, but some to advanced disease. The average number of patients in the wards during the year per diem was 167, a decrease of nine compared with last year. The average number of days in the hospital per patient was 21·3 and the aggregate number of days in the hospital for all patients was 60,078 days. As compared with the previous year the report states that while the number of patients treated this year had increased the average daily number has decreased, thus indicating a shorter average stay per patient and further indicating a more active service together with a less number of chronic and incurable cases. Of the indoor patients treated to a conclusion there were—males, 1795; and females, 1029; giving a total of 2824. The following is the classification as to religious beliefs: Protestants, 1273; Roman Catholics, 1213; and other religions, 339. Another interesting classification from the Montrealer's standpoint: citizens, 2330; strangers, 368; sailors, 115; and immigrants, 11. Of the 2824 patients treated during the year 1684 were native-born Canadians and 773 hailed from the British Isles. The death-rate has been 6·5 per cent., or if the 106 cases which died within three days were excluded 3 per cent. In the outdoor department there were 37,373 consultations, being an increase over that of last year of 2295. In the medical department there were treated 12,403 cases; surgical, 10,843; eye and ear, 6213; gynæcological, 1400; nose and throat, 2437; dermatological, 1902; dental, 60; and emergency, 2115. The ambulance made 1104 trips during the year. Dr. Charles W. Wilson, having been appointed surgeon to the Royal Canadian Regiment, has been granted leave of absence for active service in South Africa. His duties are at present being satisfactorily performed by Dr. Gilday. Dr. von Eberts, the medical superintendent, was re-appointed for another term. Mr. F. Wolferstan Thomas (since deceased) resigned the presidency, and Mr. James Crathern was unanimously elected to succeed him.

Canadian Army Medical Services.

Amongst medical men who take an active interest in our militia a good deal of satisfaction is being expressed that the Government of Canada has at last been able to get the medical service upon a proper and efficient footing. Almost since confederation in 1867 the medical officer has remained in the position that era in our politics found him up to the present time—a more or less of an ornamental appendage to

the battalion claiming his services. It was only through some personal influence or social status or political "pull" that preferment could be obtained, which all tended to emphasise the importance of placing the whole service under special organisation. Last year a general order emanated from the Militia Department at Ottawa and a scheme for organisation was proposed which has now been carried into effect. Through this order a medical staff has been established which consists as follows: one colonel (director-general), seven lieutenant-colonels, 17 majors, 22 captains, and 25 lieutenants. For the purpose of promotion the officers of the Army Medical Staff are considered as a distinct branch, and promotion from rank to rank is to take place upon the same principle as that in vogue in a regiment or corps. By this order, also, five bearer companies and five field hospitals were established on a peace footing. A bearer company is to consist of one major, two captains or lieutenants, one sergeant-major, one quartermaster-sergeant, one staff-sergeant-compounder, four sergeants, one bugler, four corporals, and 20 privates. The Halifax bearer company (No. 1 bearer company) is, however, to be kept on a war footing of 64 of all ranks. The following is the *personnel* of a field hospital: one major, two captains or lieutenants, one sergeant-major, two staff-sergeants, two compounders, two corporals, and 14 privates. Schools of instruction will be opened at once at various centres throughout the country by officers who have already qualified at the depôt of the Royal Army Medical Corps at Aldershot. Instruction will be given on infantry drill, Parts I. and II., manual of the Royal Army Medical Corps, regulations for army medical services, military hygiene returns and duties, military law, and equitation. At the close of these schools, which are to last one week, examinations will be held and two classes of certificate granted, a first class for those officers obtaining 70 per cent. of the whole number of marks and not less than 50 per cent. in any one subject; a second class to those who make 50 per cent. of the total and not less than 33 per cent. in any one subject.

Prepared for the Plague.

Owing to an outbreak of bubonic plague having been reported at Honolulu, and the undoubted appearance of the curse at San Francisco and the Diamond Head quarantine station on the Pacific coast of the United States, the eyes of the people of the Dominion have been turned with no little anxiety to our own territory in that quarter, wondering what are the facilities inaugurated by our Government for coping with the first appearance of the dread disease. The quarantine station is situated on our western shores at William's Head, under the superintendence of Dr. Watt, an active and efficient officer. This station is situated on a long narrow peninsula, distant about eight miles from British Columbia's capital, Victoria. The equipment of the station far outclasses anything of its kind in the Dominion of Canada and is said to rival, or in fact to be far superior to, any similar institution in the neighbouring Republic to the south of us. On the wharf is a moveable engine for the purpose of forcing sulphur fumes into and through the holds of the vessels, whilst the ropes which hold the visiting vessel to the wharf are carefully covered with funnel-like rat-catchers to prevent the landing of any of these long-tailed carriers of the infection. The formaldehyde process is also employed in disinfecting, and in addition there is a large tank holding over 8000 gallons of muriatic acid and bichloride of mercury contantly ready at any moment to spray the exposed surfaces of ships where fumigation would not be feasible. The arrangements are such that 600 Asiatics can be accommodated at one time. The hospitals occupy another portion of the grounds and are scientifically constructed on the pavilion plan and complete in all their arrangements. There is also a cheery home for first-class passengers at some distance from the common quarters. With such complete arrangements on our western confines the plague will have some difficulty in finding footing on Canadian or British Columbian soil.

Toronto, June 2nd.

VOLUNTARY NOTIFICATION OF PHTHISIS.—The Plymouth Town Council has adopted a scheme for the voluntary notification of phthisis, by which medical practitioners will receive a fee of 2*s.* 6*d.* for each notification in the case of private patients and 1*s.* for the notification in parish or dispensary cases.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Medical Anniversaries.

THE opening week of summer has been notable for the medical anniversaries which took place at Atlantic City, a favourite health resort on the Atlantic coast in the vicinity of Philadelphia. First came the New Jersey State Medical Society with papers and discussions on subjects of a local interest. Then came the "Confederation of Examining Boards," an organisation comprising all the State Examining Boards of the United States. These boards are devoted to the examination of persons intending to practise in their respective States and are responsible for the enforcement of the laws regulating medical practice in the several States. This was the tenth annual meeting of that body and it was very gratifying to learn of the progress of the reforms in the educational qualifications of practitioners throughout the country. In every State these boards are gradually raising the standard of education and thus sifting out the uneducated applicants in accordance with the newly-enacted laws of the States. Perhaps the most interesting and useful discussion was as to the steps to be taken to establish a uniform standard of preliminary requirements. As the General Government has no power to fix a standard of educational qualification it is of the first importance that the several States should come to an agreement and adopt a uniform standard. To that end this confederation of boards is properly exerting all its energies and has the support of the entire profession. The American Academy of Medicine, which admits to its membership only collegiates, was entertained with a variety of papers on ethical and scientific subjects. The American Medical Publishers' Association, the American Medical Editors' Association, and the Association of American Medical Colleges also held annual meetings at the same time and place. There were several other minor medical societies in session, but the great centre of attraction was the American Medical Association, which held its fifty-first annual meeting during four days. Indeed, it was the occasion of the meeting of this association that drew so many other societies to this city. The membership of the association numbers about 9000 and there were in attendance nearly 1000 physicians. The President, Professor W. W. Keen of Philadelphia, in his address discussed subjects relating to the welfare of the association and then dwelt at length upon the "needs for endowments of medical schools." He stated that in 1894 the charitable gifts and bequests in the United States amounted in round numbers to $20,000,000, in 1895 to $29,000,000, in 1896 to $34,000,000, in 1897 to $34,000,000, in 1898 to $24,000,000, and in 1899 to the enormous sum of nearly $80,000,000. Only a small portion of this amount has been bestowed upon medical schools. It was mostly given to colleges, theological schools, hospitals, museums, and libraries. He compared the theological and the medical schools. In 1898 84 theological schools reported endowments of $18,000,000 and 711 similar schools reported no endowment. In the same year 19 medical schools reported endowments of $1,906,072, while 151 medical schools reported no endowment. Yet in 1899 there were only 8000 students of theology for whom this enormous endowment was provided, as against 24,000 students of medicine, with a slender endowment of less than $2,000,000. Each theological student had the income of an endowment of $2250 provided for his aid, while each medical student had the income from $83. As against 171 chairs of theology, all endowed, there were only five in medicine. He recommended that endowments of medical colleges should be classed in three categories—namely, first, the endowment of professorships; second, the endowment of the laboratories; and third, the endowment of post-graduate scholarships and research fellowships.

Typhoid Fever among the American Soldiers in 1898.

Professor Vaughan of the University of Michigan and late Division Surgeon United States Volunteers has reported the results of the commission appointed by the Surgeon-General to study typhoid fever as it appeared among the American soldiers. In accordance with instructions this commission visited the national encampments and inspected most of the regiments. It spent about 18 months in an examination of the medical records of these commands and accumulated a vast amount of information which is embodied in a report

about to be submitted to the Surgeon-General. The conclusions of the commission are as follows. Every regiment in the United States service during 1898 developed typhoid fever. More than 90 per cent. of the volunteer regiments developed typhoid fever within eight weeks after assembling at the state encampments. Most, probably all, of the regular regiments developed typhoid fever within less than eight weeks after going into camp. The fever not only appeared in every regiment in the service, but it became epidemic both in the small encampments of not more than one regiment and in the larger ones consisting of one or more corps. It became epidemic in camps located in the Northern as well as those located in the Southern States. Neither the miasmatic nor the pythogenic theories of the origin of typhoid fever is supported by these investigations, but they do confirm the doctrine of the specific origin of typhoid fever. Camp pollution was the greatest sin committed by the troops of 1898. It may be stated in a general way that the number of cases of typhoid fever in the different camps varied with the method of disposing of excretions. The tub system of the disposal of fæcal matter and the regulation pit did not prove satisfactory in permanent camps. Infected water was not an important factor in the spread of typhoid fever, but flies undoubtedly served as carriers of infection. It is probable that the infection was disseminated through the air in the form of dust. A command badly infected by typhoid fever does not lose the infection by simply changing the location, for it carries the specific agents of the disease in the bodies of the men, in their clothing, bedding, and tentage. About one-fifth of the soldiers in the national encampments of the United States in 1898 developed typhoid fever and army surgeons correctly diagnosed a little less than half the cases. The continued fever recognised among the soldiers the commission decides was typhoid fever. The belief that errors in diet with consequent gastric and intestinal catarrh induced typhoid fever is not supported by these investigations. The percentage of deaths among cases of typhoid fever was about 7·5. The deaths from typhoid fever were more than 80 per cent. of the total deaths.

Victims of Lightning in the United States.

The Superintendent of the United States Weather Bureau states that the loss of life by lightning in this country last year was greater than in any year since statistics began to be collected. 562 persons were killed instantly or suffered injuries from which death soon resulted and 800 persons were injured, many of them suffering from physical shock, others from painful burns, and some from temporary paralysis of portions of the body. Paralysis of the arms or legs was the most common form of injury. The greatest number of fatalities, or 45 per cent., occurred in the open; the next greatest number, or 34 per cent., occurred in houses; 11 per cent. occurred under trees; and the least number, 9 per cent., happened in barns. A number, mostly women, were killed while taking clothes from wire lines or while near the lines during a thunderstorm.

Death of Dr. Edward O. Shakespeare.

This eminent man of science died suddenly from angina pectoris on June 1st, aged 54 years. Dr. Shakespeare devoted himself in his earlier years to ophthalmic surgery, to which he made some notable contributions. Later he became interested in sanitary investigations and on one occasion was commissioned by the Government to visit India and other countries for the purpose of reporting on cholera. The results of a year's study of cholera in the Delta of the Ganges and the chief cities of India were embodied in a very voluminous report, published by Government, which has been regarded as an authority on the question of the propagation of that disease. In 1894 he was commissioned to attend the Ninth International Sanitary Conference which was called by the French Government and which met in Paris. He took a leading part in that Conference and many of the rules adopted by that body governing the pilgrimages to Mecca were advocated by him. During the war with Spain Dr. Shakespeare was appointed by the Surgeon-General one of a commission to investigate the causes of typhoid fever among the soldiers in camp. His last days were spent in the completion of the report of the commission, which is a work of great magnitude and importance.

Responsibility of a Hospital for the Acts of a Nurse.

A verdict of $10,000 has been obtained against St. Vincent's Hospital of this city by a patient who was severely burned after an operation by a hot-water bottle placed against her leg while she was still under the influence of ether. It appeared on the trial that the person who placed the bottle against her leg was not a trained nurse but a pupil in the defendants' training school. The defence was based on the fact that the hospital was devoted to charity and on that plea chiefly two previous juries had failed to convict of culpable negligence. It was proved, however, that this patient was treated in the "pay ward" and that the plea of charity did not apply to her case and hence the verdict was against the hospital.

The Progress of the Bubonic Plague.

It is becoming daily more and more apparent that this pest can be arrested and stamped out even where all the conditions are most favourable for its propagation when modern scientific methods of sanitation are intelligently and rigorously applied. The outbreak in Honolulu is a striking instance of the enormous value of a well-appointed and well-equipped health organisation in a municipality which is allowed to exercise its authority with a free hand. The infection of the plague was there introduced into a community peculiarly susceptible by its location, its filthy habits, and its reckless opposition to all sanitary rules and restraints. It began to spread like fire in tinder and would, judging by its previous history, soon have involved the whole native Chinese and Japanese population. But the health authorities came at once to the rescue, and, like a well-organised fire department, first directed all their energies to the task of isolating the infected from the uninfected, and then attacked the infection itself. The result has justified measures that were regarded as unnecessarily severe, for the plague was at once brought under control and then exterminated. The same result has been secured at San Francisco and in a measure in Manilla. The lesson that we have learned will prove of incalculable value, not only in our future contests with this oriental pestilence, but with all other communicable diseases.

June 18th.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE following were among the principal amounts received at the Mansion House in aid of this Fund up to noon on Thursday:—

	£	s.	d.
St. Michael's, Chester-square	1156	0	0
Chislehurst Parish Church (including £100 from Mr. Richard Foster)	290	0	0
St. Paul's Presbyterian Church, Westbourne-grove	103	0	0
St. John's Presbyterian Church, Kensington	82	0	0
St. Paul's Cathedral	255	0	0
St John's Wood Presbyterian Church	114	0	0
All Saints, Ennismore Gardens	487	0	0
Blackheath Congregational Church	154	0	0
St. Stephen's, South Dulwich	191	0	0
Union Chapel	130	0	0
St. Alban's, Streatham	182	0	0
St. Mark's, North Audley-street	107	0	0
All Saints, North Peckham	170	0	0
"F. H."	1000	0	0
St. Barnabas, Addison-road	100	0	0
St. Mary's, Kilburn	114	0	0
St. James's, Kidbrook	219	0	0
Holy Trinity, Sydenham	197	0	0

The total amount received by noon on Thursday, July 28th, was £24,000.

WELLS, SOMERSET.—At the meeting of the Wells Town Council held on June 18th it was decided to carry out the septic system of sewage disposal at an estimated cost of £4500.

THE NEW BELGRAVE HOSPITAL FOR CHILDREN.—The foundation-stone of this institution was laid on June 27th, by the Princess Henry of Battenberg. The site, which adjoins St. Mark's Church, Kennington, is the centre of a poor and populous district. £17,000 of the £50,000 required for initial expenses have been provided. The cost of the new site is £4000; the centre block and west wing will cost £25,000, the east wing £8000, the south wing £6000, and the out-patient department £5000. It is intended in the first instance to erect the centre block and west wing and the out-patient department. Purses to the amount of £200 were received by her Royal Highness.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In June the following candidates passed in the subjects indicated:—

Surgery.—J. M. Anderson, Aberdeen and Middlesex Hospital; J. R. Clemens, St. Thomas's and London Hospitals; R. V. Cowey (Section II.), Edinburgh and St. Mary's Hospital; W. A. C. Cox (Section II.), St. Mary's Hospital; H. J. De Saram, Middlesex Hospital; W. D. French (Sections I. and II.), and T. R. Griffiths, University College Hospital; J. H. Kellgren (Section II.), Cambridge and St. George's Hospital; B. Lewitt and A. H. L. Newstead, St. Mary's Hospital; W. P. R. Newth, St. Thomas's Hospital; E. C. Pratt, Birmingham; and A. T. Spanton (Section I.), Cambridge and St. George's Hospital.

Medicine.—E. A. Dunn (Section I.) and E. Evans (Sections I. and II.), Royal Free Hospital; A. W. H. Grant (Sections I. and II.), Charing-cross Hospital; J. H. Kellgren (Sections I. and II.), Cambridge and St. George's Hospital; J. Klein (Sections I. and II.), St. Mary's Hospital; B. Rowlands, St. Bartholomew's Hospital; M. H. Style (Sections I. and II.), Royal Free Hospital; and T. Young (Section II.), St. Bartholomew's Hospital.

Forensic Medicine.—E. A. Dunn and E. Evans, Royal Free Hospital; A. W. H. Grant, Charing-cross Hospital; J. H. Kellgren, Cambridge and St. George's Hospital; J. Klein, St. Mary's Hospital; G. R. Lucas, Charing-cross Hospital; S. Page, Birmingham; B. Rowlands, St. Bartholomew's Hospital; M. H. Style, Royal Free Hospital; and T. Young, St. Bartholomew's Hospital.

Midwifery.—S. F. Cneesman, Charing-cross Hospital; W. T. Colyer, Cambridge; M. B. Dawson, Middlesex Hospital; E. Evans, Royal Free Hospital; F. J. F. Jones, Guy's Hospital; J. Klein and A. H. L. Newstead, St. Mary's Hospital; A. T. Spanton, Cambridge and St. George's Hospital; M. H. Style, Royal Free Hospital; and H. V. Swindale, Middlesex Hospital.

The diploma of the society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—Messrs. J. M. Anderson, H. J. De Saram, W. D. French, T. R. Griffiths, J. H. Kellgren, B. Lewitt, W. P. R. Newth, and T. Young.

UNIVERSITY OF CAMBRIDGE.—At the examinations for medical and surgical degrees, Easter Term, the following candidates were successful in the subjects indicated:—

THIRD EXAMINATION.

Part I.—G. F. Barham, B.A., and A. E. Bodington, M.A., Caius; A. R. M. Brenan, B.A., Trinity; J. M. Brydone, Jesus; F. J. Child, B.A., Christ's; H. N. Clarke, B.A., and J. S. Clarke, B.A., Caius; J. G. Cooke, B.A., Sidney Sussex; K. E. Crompton, B.A., Caius; G. W. Deeping, B.A., Trinity; J. B. Dunlop, B.A., Sidney Sussex; W. E. M. Ede, B.A., King's; A. Emerson, B.A., Caius; R. L. V. Foster, B.A., King's; T. B. Gilbart-Smith, B.A., Trinity; W. H. C. Greene, B.A., Corpus Christi; E. B. Leech, B.A., Christ's; N. Maclaren, B.A., Trinity; A. S. Mellor, B.A., King's; C. H. Miller, B.A., J. C. Newman, B.A., and G. H. Orton, B.A., Trinity; T. W. Paterson, B.A., Caius; J. S. S. Perkins, B.A., St. John's; J. C. S. Rashleigh, M.A., and L. Reynolds, B.A., Trinity; H. H. Riddle, B.A., Peterhouse; J. C. A. Rigby, B.A., Caius; E. W. S. Rowland, B.A., H. Selwyn; L. B. Scott, B.A., Christ's; G. A. C. Shipman, B.A., Trinity; J. L. Timmins, B.A., Emmanuel; R. H. Urwick, B.A., Trinity; H. Walker, B.A., King's; T. H. E. Watts-Silvester, B.A., and R. F. Williams, B.A., Caius; W. W. Wingate-Saul, M.A., Trinity; and H. C. S. Woodward, M.A., Downing.

Part II.—S. Bousfield, M.A., Caius; J. Bradford, Emmanuel; H. P. Bradley, B.A., and G. V. Bull, B.A., Caius; T. Burfield, B.A., Emmanuel; C. J. Coleman, B.A., Trinity; B. J. Collingwood, B.A., Caius; W. S. Darby, B.A., and W. M. Fletcher, M.A., Trinity; J. H. P. Fraser, B.A., Jesus; O. F. F. Grünbaum, M.A., Trinity; J. Gutch, M.A., Christ's; D. G. Hall, B.A., Emmanuel; A. C. Hill, M.A., Trinity; T. E. Holmes, B.A., G. F. Lobb, B.A., and J. L. Lock, B.A., Caius; J. W. Malim, B.A., Christ's; H. N. Matthews, B.A., J. C. Matthews, B.A., and F. J. Nicholls, St. John's; L. J. Paton, B.A., Caius; A. C. Pearson, B.A., Sidney Sussex; J. H. Philbrick, B.A., and G. R. Slade, M.A., Trinity; J. G. Taylor, B.A., and T. S. Taylor, B.A., King's; R. A. Walker, B.A., Clare; and A. Whitmore, B.A., and W. M. Willoughby, B.A., Caius.

The Council of the Senate have nominated Professor Sir Michael Foster, K.C.B., to represent the University on the Council of the Jenner Institute of Preventive Medicine.—Mr. A. W. Hill, B.A., King's College, and Mr. L. Lewton-Brain, B.A., St. John's College, have been appointed Demonstrators of Botany.—Mr. H. Nicholls, M.A., of St. John's College, was on June 19th admitted to the degree of M.D.—The Harkness Scholarship in Geology and Palæontology has been awarded to Mr. E. E. Walker, Trinity College.—The Professor of Pathology announces a series of ten courses of instruction in Pathology, Morbid Anatomy, Bacteriology, &c., to be given during the Long Vacation, beginning on July 5th.—The "Summer School" of Medicine for qualified practitioners, as announced last week, has been abandoned owing to the small number who intimated their wish to attend it.

UNIVERSITY OF BRUSSELS.—At the June examination the following practitioners satisfied the examiners and obtained the M.D. degree:—

W. Grantham Hill, B. Burnett Ham, J. L. Atkinson, and W. Gilbertson, London; C. S. Davies, Bishops Stortford; T. E. Pallett Earls Colne; G. H. Brand, Northampton; and Collingwood Fenwick, H. Hipwell, and S. Whitaker, London.
There were 13 candidates.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—FELLOWSHIP EXAMINATION.—The following gentlemen having passed the necessary examination have been admitted Fellows of the College:—Mr. R. C. B. Maunsell, M.B., B.Ch., B.A.O. Dub., and Mr. H. J. Satchwell, L.R.C.P. and L.R.C.S. Irel.

UNIVERSITY COLLEGE, LONDON.—The following is a list of the prizes awarded in the Faculty of Medicine for the winter session, 1899–1900:—Entrance scholarships: Bucknill Scholarship, £120, G. Hall; Int. Med. Course, £57 15*s.* each, J. A. Ferrière and E. Mapother*; Final M.B. Course, £79 16*s.* each, C. S. Parker* and T. L. Llewellyn. Atchison Scholarship (£55 per annum for two years): R. E. Lloyd. Bruce Medal: R. E. Lloyd. Physiology: Senior class, gold medal, A. M. H. Gray; third class, G. S. Hett; junior class, silver medal, R. A. Greeves. Certificates, 2† eq., J. A. Ferrière, G. Hall, 4,† R. S. Woods, and 5,† E. G. Perodeau; second class, A. G. C. Findlay; third class, N. S. Finzi,* P. M. Roberts, and C. S. White.* Anatomy: senior class, 1st silver medal, A. M. H. Gray, and 2nd silver medal, G. S. Hett; third class, C. H. Berry and M. W. Stewart-Smith; junior class, silver medal, R. A. Greeves, and certificates, 2,† G. Hall, 3,† and C. D. Holdsworth; second class, J. A. Ferrière, G. E. O. Williams, and R. S. Woods; third class, W. Appleyard, A. J. Blaxland, H. Farncombe, and A. G. C. Findlay. Medicine: second class, L. G. Hopkins, A. E. Jones, and R. E. Lloyd. Surgery: gold medal, R. E. Lloyd; silver medal, L. G. Hopkins; second class, A. E. Jones. Pathology, Morbid Histology, and Bacteriology: Tuke silver medal, T. L. Llewellyn; third class, C. S. Parker.* Practical Surgery: Erichsen prize, L. G. Hopkins; certificates, 2,† S. H. Bown, 3,† O. L. Addison, and 4,† T. C. Savage; second class, S. Bree, R. E. Lloyd, H. W. Reynolds, and A. N. Stevens. Clinical Medicine: senior class, Fellowes gold medal, H. W. Reynolds; Fellowes silver medal, A. E. Jones; certificate, 3,† T. C. Savage; second class, D. L. Davies, A. Emerson, L. G. Hopkins, R. E. Lloyd, and G. A. Upcot-Gill*; Junior class, Fellowes silver medal, A. F. Horn; certificates, 2,† G. E. Waugh, 3,† C. S. Parker,* and 4,† J. E. Stratton; second class, J. B. Burt, W. T. Crawford, L. A. E. de Zilwa, T. L. Llewellyn, and W. Parsons*; third class, J. C. Fleming and F. J. Lawson.* Clinical Dental Surgery: silver medal, L. G. Hopkins; certificates, 2† eq., A. E. Jones and R. E. Lloyd.

* Former pupil of University College School.
† Obtained the number of marks qualifying for a prize.

MEDICAL DEFENCE UNION, LIMITED.—The usual monthly council meeting of the union was held at the registered offices on June 21st, Dr. Walter Griffith, the President, being in the chair. An election of candidates took place, the total number of new members being 270. The general secretary read a draft letter which he had prepared in the matter of a report to the General Medical Council concerning the granting of certificates to persons other than medical practitioners by certain associations and lying-in institutions and which certificates are taken by the holders and the public as qualifying them to practise as midwives. The council adopted the letter and ordered it to be forwarded to the General Medical Council with a recommendation from the union to the following effect—viz., "That it is desirable in the interests of the public that medical practitioners either individually or collectively by association should not be allowed to issue any document which in any way can be taken by the holder or the public as granting authority to practise or which can be used to cover any practice of medicine, surgery, or midwifery, saving in the case of persons examined by duly appointed examining bodies under the supervision of the General Medical Council through their inspectors of examinations." Directions were given to the executive to call the attention of the council of the Royal British Nurses' Association to the heading in their register of nurses, Appendix B, and also to the use of the words "Diploma, London Obstetrical Society, &c.," appended to certain nurses' names. The union suggested to the Royal British Nurses' Association that the heading referred to—viz., "List of Nurse-members who have Obtained Certificates Qualifying them to Act as Midwives"—i.e. to practise midwifery—was likely to mislead the public into the belief that these

nurses were duly qualified practitioners and that an alteration was desirable in the title to the appendix. A medical practitioner who was proved to be "covering" the practice of a much-advertised self-styled "aural institute" was ordered to be reported to his licensing corporation for unethical conduct. An important report drawn up by the solicitors of the union with regard to the present law relating to the keeping for gain of persons of unsound mind by registered practitioners who possessed no licence from the Lunacy Commissioners was read and ordered to be entered upon the minutes. The report urged an amendment in the lunacy law with regard specially to the definition of a "lunatic" and steps were directed to be taken to bring this question before the Lord Chancellor. A report in reference to the admission by school boards of certificates of ill-health of children signed by persons other than registered medical practitioners was ordered to be extended and dealt with later. Owing to the numerous cases which were brought before the council at each monthly meeting it was decided to hold executive council meetings regularly every 14 days in order to shorten the sittings if possible. Action was directed to be taken in certain instances where members were threatened with writs for alleged negligence in cases attended and reports were made by the solicitor and general secretary in other cases in which actions threatened had collapsed when it became known that the union was prepared to defend. A report was made by the solicitors in a case of dispute between a medical member and a druggist in reference to the ownership of prescription books kept by the latter which contained solely the prescriptions for patients for whom the druggist had dispensed medicines at the instance and at the charge of the practitioner. A satisfactory result of the difference was reported, but it was decided to recommend medical men who handed their dispensing over to local druggists that in order to avoid any chance of dispute they should use their own books in which the prescriptions could be copied in future.

CHURCH SANITARY ASSOCIATION.—The eighth annual meeting of this association was held last week at the Church House, Westminster.—Dr. W. Collingridge, sanitary officer for the Port of London, who presided, emphasised the need for the society's existence. A question which urgently demanded attention was the vital necessity for cleanliness in the preparation, storage, and use of food. Animals should be examined before slaughter by a competent authority. Municipal slaughter-houses would do much to prevent cruelty and undoubtedly much to prevent unfit food from being consumed.—The Rev. F. Lawrence, honorary secretary, reported that sermons had been preached during the year at home and abroad and efforts made to induce legislation respecting slaughter-houses, overcrowding, and the like. He appealed for additional funds.—The report was adopted on the motion of Dr. Christopher Childs, seconded by General Lowry.—Canon Rawnsley moved that it was desirable that preachers and all persons of influence should aid in preventing diseases and fostering the health of the people.—Mr. Hugh Munby seconded, and the Rev. A. M. Mitchell supported the motion, which was carried.—On the motion of Major W. C. Poole, R.A.M.C., it was agreed that "this meeting is of opinion that hygiene should be taught in elementary schools."—Miss Ethel Springett read an interesting paper on the subject of consumption.—Resolutions of thanks to the chairman and secretary concluded the proceedings.

CHARING-CROSS HOSPITAL MEDICAL SCHOOL.—The presentation of the scholarships, medals, prizes, and certificates awarded during the summer session of 1899 and the winter session of 1899–1900 took place on June 26th. Mr. H. Beerbohm Tree occupied the chair. The Dean, Dr. Montague Murray, in his report for the current year, stated that the number of new students had been 88 as contrasted with 82 in the previous year. The only important changes in the teaching staff were the appointment of Professor Moore of the Yale University to the Lectureship on Physiology, and of Dr. Marrett Tims to the Lectureship on Biology. In the school buildings important improvements had been effected. A new staircase had been added to the Museum and the electric light had been introduced. Reference was made to the large number of old and of present students now serving in South Africa, headed by Mr. C. Gibbs, one of the assistant surgeons, who is now senior surgeon to the Langman Hospital. The Dean announced that the new academical year would open on the evening of Oct. 1st with a conversazione given by the Students' Societies, that the Huxley lecture would be delivered on Oct. 2nd by Lord Lister, President of the Royal Society, and that the Old Students' dinner would be held on the same evening at the Hotel Cecil. The renovations and additions to the hospital had been commenced, and in two years' time the Dean anticipated that a considerable portion of the new buildings would be ready for occupation. Mr. Beerbohm Tree, in presenting the prizes, referred to the sympathy and regard with which the members of his own profession were ever held by members of the medical profession.

MEDICAL GOLF TOURNAMENT, 1900.—This tournament was held under medal play regulations on May 10th by permission of the Wembley Golf Club on their links. The winner was Mr. Percy Furnivall.

FALMOUTH.—A man at Falmouth was on June 19th fined £3 and £1 15*s.* costs for entering a cab whilst suffering from scarlet fever and also for mingling with the public in the street.

VACCINATION GRANT.—Mr. Richard Macartney, L.R.C.P., L.R.C.S., L.M. Edin., of Cinderford, Gloucestershire, public vaccinator for the fourth district, Westbury-on-Severn Union, has been awarded a grant for successful vaccination.

PERMANENT APPOINTMENT OF A MEDICAL OFFICER OF HEALTH.—Mr. C. M. Fegen, M.R.C.S. Eng., L.R.C.P. Edin., D.P.H., has been appointed permanently medical officer of health to the Croydon Rural District Council at a salary of £600 per annum. The appointment has been confirmed by the Local Government Board.

COMPLIMENTARY BANQUET.—Mr. Daniel Dougal, M.D., F.F.P.S. Glasg., of East Overton, Strathaven, was entertained on June 22nd in the Public Hall to a complimentary dinner and presented with a gold watch on his retiring from active practice and leaving the district after a life-long connexion with it. A considerable sum of money has also been subscribed and Dr. Dougal liberally assented to hand over the balance to the committee to appropriate as they deem most advantageous for the general public.

THE WOOLWICH, PLUMSTEAD, AND CHARLTON MEDICAL UNION.—At the last meeting of this union the following resolutions were passed:—"1. That medical officers of friendly societies be recommended to decline to attend juvenile members of clubs for a less sum than shall be agreed upon by members of this union. 2. That the union's resolution, 'That the same annual subscription with respect to juvenile clubs should be required as for men's clubs—viz., 4*s.* a year per member,' be taken to apply to clubs taking children over eight years of age only. 3. That under eight years of age children should be only taken at 8*s.* a year."

BRUSSELS MEDICAL GRADUATES' ASSOCIATION.—The twentieth annual general meeting of this association will take place at the Café Royal, Regent-street, W., on Tuesday, July 3rd, at 6.30 P.M. At 7.30 P.M. the members and their friends will dine together, and among the guests are expected Sir Walter Foster, M.P., Dr. G. Vivian Poore, Dr. T. Gilbart Smith, Dr. Dawson Williams, Mr. Howard Marsh, and Dr. Clement Godson. Any Brussels medical graduate desiring to be present is requested to communicate with the honorary secretary, Dr. Major Greenwood, 243, Hackney-road, N.E. Tickets for the dinner are 7*s.* 6*d.* each, exclusive of wine.

DEATHS FROM PTOMAINE POISONING.—An inquest was held at Carmarthen on June 15th upon the wife of the head constable of that town who had been taken ill after eating some shrimps on May 26th and had died on June 5th. Medical evidence showed that death had resulted from ptomaine poisoning and a verdict to that effect was returned.—A man, his wife, and seven children ate roast pork for dinner at Plymouth on June 10th and within a few hours all, with the exception of two boys, were seized with vomiting. One of the children, a boy, aged five years, died on the following day. At the inquest held on June 13th the medical evidence showed that death was due to ptomaine poisoning and a verdict was given by the jury to that effect. This latter case is referred to in another column.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Hours of Labour in Shops.

LORD AVEBURY having failed to induce the Government to take steps this session for the appointment of a Parliamentary inquiry into the hours of labour in shops has announced that he will himself move for the appointment of such an inquiry at the commencement of next session.

Registered Companies and Medical Practice.

The Bill of the Government to amend the Companies Acts has been read a second time in the House of Commons and referred to the Grand Committee on Trade. The third clause of the Bill says that it shall be unlawful for a company to carry on the profession or business of a physician, surgeon, dentist, or midwife, and if any company contravenes this enactment it shall be liable on summary conviction to a fine not exceeding £5 for every day during which the contravention happens. Both Mr. RITCHIE (the Minister in charge of the Bill) and Mr. BALFOUR assured the House that the Government are anxious to see the measure passed into law during the present Parliament.

Midwives Bill.

The Midwives Bill may now be regarded as dead so far as the present session of Parliament is concerned. The Government allowed two Wednesdays for the consideration of private Members' Bills, and on the second of these Wednesdays (June 27th) the Bill was reached but no progress was made with it.

HOUSE OF LORDS.

TUESDAY, JUNE 26th.

The St. Pancras Lunacy Scandal.

Lord RUSSELL OF KILLOWEN raised this question in debate and asked the Government whether they intended to take any proceedings. His lordship gave an account of the system which has recently been exposed. Under this system, he said, there was a temptation to the relieving officer to take up an insane person, to take such a person before a particular medical man to the detriment of others as well qualified but more scrupulous, and to take patients, not to public institutions where they could be kept at a cost of something like 19s. a week, but to private asylums where the cost was two guineas or more. There was reason, it seemed, to believe that the system, whilst not universal, was not confined to St. Pancras. He had been waited upon by a member of the vestry of St. Matthew's, Bethnal-green, where they found that this dishonest state of relations existed. They had drawn the attention of the Local Government Board and the Lunacy Commissioners to it. The latter said they had no authority to deal with the matter, and the Local Government Board only held an inquiry after considerable delay and continued pressure.—The LORD CHANCELLOR, after commenting on the seriousness of the subject, said that the attention of the Commissioners in Lunacy had been called to the Bethnal Green case as long ago as last November and they invited the Public Prosecutor to consider whether it might not be made the subject for a prosecution of the persons concerned. The Public Prosecutor, after taking the opinion of counsel, came to the conclusion that the Act of 1889, Lord Randolph Churchill's Act, would not reach these persons. His own attention had been drawn to the case by the Lunacy Commissioners, who forwarded to him a draft clause for insertion in the Bill amending the lunacy laws. This Bill had passed the House of Lords and was now before the other House. He believed it was urgently demanded, not only for the particular matter now under review, but on other and general grounds, though he was afraid, having regard to the period of the session which had been reached, that the measure was in some peril of not being passed this session.—The Earl of KIMBERLEY asked what action, if any, had been taken by the Local Government Board.—The LORD CHANCELLOR said that he had received a communication from the Local Government Board on the subject. In the course of this communication the Local Government Board stated that the charges in the Bethnal Green case appeared to be well founded, and as it was alleged that similar practices prevailed in another Poor-law union in the metropolis they proposed to address a circular letter to boards of guardians on the subject.

HOUSE OF COMMONS.

THURSDAY, JUNE 21ST.

Medical Officers in Volunteer Corps.

Mr. BILLSON asked the Under Secretary of State for War if the army order relating to the payment of volunteers in camp would limit the payment to medical officers to one such officer for each corps, so that when a corps was entitled to two or more medical officers all but one would have to pay their own expenses; and, if so, why medical officers should be placed in such a position.—Mr. WYNDHAM replied: The order allows pay for one medical officer in each unit, one additional for each brigade, and three for each bearer company. This is considered sufficient.

The Mortality Averages for Liverpool.

Sir JOHN WILLOX asked the Secretary to the Treasury whether his attention had been drawn to the last report of the medical officer of health of the city of Liverpool, in which allegations were made of the inaccuracy and unreliability of the census returns of the last census and the consequent errors in the calculation of the mortality averages for the decennial period; and whether measures would be adopted to ensure greater correctness in taking the next census by the employment of more competent enumerators or otherwise.—Mr. CHAPLIN, who replied to the question, said: The question of my hon. friend appears to be founded on a misapprehension. No allegations are made in the report referred to of the inaccuracy and unreliability of the census returns. The medical officer appeared to have been referring to the estimates of population in the years between 1881 and 1891. These estimates were based on the increase in population in the 10 years between 1871 and 1881, and the result of the last census showed that in the case of Liverpool this rate of increase had not been maintained. There appears, however, to be no reason to suppose that the census returns themselves were inaccurate.

Medical Examination under the Workmen's Compensation Act.

Mr. WOODS asked the Home Secretary if, under Clause 11 of the First Schedule of the Workmen's Compensation Act, 1897, a workman was entitled to submit himself for examination by the qualified medical practitioner appointed for the district in which he resided by the Secretary of State, when the medical practitioner appointed by his employer had given a certificate upon his condition with which he was not satisfied, although the case had not been before a committee, arbitrator, or judge, in consequence of the employer and the workman having previously agreed to pay and receive a fixed weekly sum as compensation.—Sir MATTHEW WHITE RIDLEY replied: The provisions of Paragraph 11 of the first schedule of the Workmen's Compensation Act apply to any workman "receiving weekly payments under the Act." Whether any particular case of agreement is "under the Act" is a question which can only be decided authoritatively on the facts of the case by a court of law and I am unable to express an opinion on it in general terms.

Soldiers Invalided from South Africa.

Sir EDWARD GOURLEY and other Members called the attention of the Under Secretary of State for War to the case of Private Mitchell of the Wiltshire Regiment, who was shot in both ankles at the battle of Modder river and invalided home.—Mr. WYNDHAM replied: There are over 7000 beds reserved in the various military hospitals for private soldiers invalided from South Africa. On reaching convalescence the soldier is transferred to a convalescent home. We have ample accommodation for the first stage of recovery in hospitals and for the second in homes. But many soldiers prefer to proceed on sick furlough to their friends. This is allowed when their health justifies it. They are in that case provided with sufficient funds and with a printed statement for their guidance which contains this paragraph: "Soldiers on furlough who require medical aid shall apply for it to the nearest military station. When this is impracticable they may apply to a civil practitioner, to whom they will show this furlough paper, and who will be allowed to charge for attendance at the rate laid down on Army Form O, 1667." Arrangements had been made to send Private Mitchell to a convalescent home, but at his own request he was allowed to go on furlough to Croydon. On leaving hospital he received £7 17*s.* 6*d.* pay. Private Mitchell states that the people with whom he had intended to stay had left Croydon. He accordingly proceeded to London and feeling ill went to the Morley Hotel, 112, Lambeth-road. His health did not improve and when he had spent two days and two nights in bed the manager sent for a doctor who ordered his removal to the infirmary. A gentleman at the hotel applied to the commanding officer, St. George's Barracks, for his removal to a military hospital. The reply did not arrive before his removal. He was accordingly visited in the infirmary and removed in a military ambulance to the station hospital in Rochester-row. I beg to thank the hon. Members who by raising this question have given me an opportunity of stating the facts at a length which will not, I hope, be considered excessive in view of its importance. There has been much comment on this case and I shall be obliged if the press will give equal publicity to the fact that civilians who find a soldier left stranded on their hands should apply to the nearest military authority and not despatch him incontinently to a pauper institution.

FRIDAY, JUNE 22ND.

The Extermination of Rabies.

During a debate in committee of supply on swine fever and the outbreak of foot and mouth disease in Norfolk Mr. WALTER LONG, President of the Board of Agriculture, said he would like to take the opportunity of acknowledging the great debt of gratitude he owed to the medical and scientific men of this country for the uniform support they had given him from the commencement of his labours in connexion with rabies and also to the members on both sides of the House for the support they had given him in spite of the unpopularity and difficulties it had brought upon them in their constituencies. He was glad that their labours had been so successful, for he believed that rabies had been practically exterminated, and, with a loyal obedience to the regulations the Department had thought it necessary to impose, he believed there was no reason why they should not hope to protect the country against any fresh outbreak of this most terrible disease.

The Sale of Food and Drugs Act.

Mr. WALTER LONG, questioned on the administration of the Sale of Food and Drugs Act of last year, said that he adhered to the view he had before expressed, that the main object of the Act was to ensure local action against adulteration, and the function of the Board of Agriculture was to exhaust every effort in urging, and, as far as they could, compelling, discharge of this duty before taking action themselves. Nothing could be more disastrous than for the central authority to be ready to do the work which rightly fell to the local authority. To do that would inevitably lead to dilatory and neglectful administration. So far as he was aware the operation of the Act of last year had been most satisfactory. The Treasury had given assistance and local authorities had been made fully acquainted with the requirements of the new Act, and he had every reason to believe that the exercise of its power by the department had led to vigorous administration by local authorities. The department would leave no stone unturned to make the Food and Drugs Act a success and to put an end to the adulteration of food.

The St. Pancras Lunacy Scandal.

In Committee of Supply, when the vote for the salaries and expenses of the Commissioners in Lunacy in England was taken, Mr. BURNS called the attention of the Attorney-General to what he described as a gross scandal in one of the branches of the Lunacy Commissioners' work. Some weeks ago it was discovered that five relieving officers employed by the St. Pancras Board of Guardians had been trafficking

with the owners of private asylums in London, so that lunatics who ought properly to have gone to the asylums controlled by the London County Council or some other public authority and there been maintained at a cost of 11s. per week, had been diverted to private asylums where the weekly maintenance charged ranged from 35s. to 40s. The five officers admitted that they had received presents and sums of money from the private asylum owners. The officials were censured by the guardians, but he was of opinion that they ought to be dismissed. There was a feeling that this sort of thing was somewhat general and he hoped the Attorney-General would have a special inquiry made.—The ATTORNEY-GENERAL (Sir Robert Finlay) said that if the facts had been correctly reported to the hon. Member they disclosed an offence of a very serious kind committed both by the relieving officers and by those who were alleged to have bribed them. He hoped, however, the hon. Member was mistaken in supposing that the practice was at all common, and he assured him that the Lunacy Commissioners would investigate with the utmost vigour the management of any establishment where it was shown the practices complained of prevailed.—Sir WALTER FOSTER, after speaking of the statement of the Attorney-General as satisfactory, said that the Member for Battersea (Mr. Burns) had rendered a public service in calling attention to the management of private lunatic asylums.

TUESDAY, JUNE 26TH.

Sunstroke at Aldershot.

Dr. FARQUHARSON asked the Under Secretary of State for War if he could state how many cases of sunstroke in connexion with the Aldershot review had been treated in hospital, what was the average duration of their stay, and whether any of the cases were reported as severe or dangerous; and whether the principal medical officer at Aldershot was consulted as to the propriety or otherwise of holding the field day on June 11th.—Mr. WYNDHAM: The total number of cases was 62; the duration of stay in hospital of those discharged was 10 days; 14 are still in hospital; 29 of the cases were considered severe. The general officer commanding did not consult the principal medical officer, nor was there any ground for doing so, since exceptional heat was not anticipated.

Inoculation for Enteric Fever.

Several questions were addressed to the Under Secretary of State for War with reference to the results of inoculation against enteric fever performed on soldiers going to South Africa. Mr. WYNDHAM replied that medical records showing these results were being compiled in South Africa but that the statistics at present available were not sufficient to enable him to give a conclusive reply. He doubted whether it would be possible to report on the subject before the end of the war.

MIDWIVES BILL.

DEBATE IN THE HOUSE OF COMMONS.

On Wednesday, June 27th, in the House of Commons, the order for the consideration of the Midwives Bill as amended in the Grand Committee on Law was reached at a quarter to five o'clock, that is to say, three-quarters of an hour before the time when the discussion of contested business must, by the rules of the House, cease.

Mr. GRIFFITH-BOSCAWEN moved that the Bill be considered upon this day three months—the formula for the rejection of a measure. The hon. Member said that he knew it was rather a strong order when a Bill had been read a second time by the House and considered and amended by a Grand Committee, to move that it be not considered, but in this case there were special reasons for the course he had adopted. First of all there was the great importance of the Bill and the necessity for the House considering its provisions very carefully and realising their full effect. Another reason was that the Bill had never had any proper consideration from the House. It came on for second reading most unexpectedly on an occasion when, to the astonishment of everybody, the business of the Government was suddenly concluded and when there was a very small attendance of members. The fact was that there had been no real or adequate discussion of the provisions of the Bill in the House. Then it went to the Standing Committee. Now reference to a Standing Committee was an excellent plan for Government Bills in which a large number of members were interested, but it was most unsatisfactory in the case of a private member's Bill, except, perhaps, from the point of view of the particular private members interested in the measure. By means of a little careful whipping any private member's Bill in which only a few members were interested could be got through a Standing Committee. This Bill was rushed through the Standing Committee and now that it came back to the House the House should carefully consider whether or not it should be allowed to proceed. He submitted that the Bill was contrary to the whole tendency of legislation in these matters in recent years. The whole tendency of recent legislation had been to insist upon a higher medical standard, to substitute science for what he might call quackery. This Bill went in quite the opposite direction. It proposed to give a certain bogus certificate to midwives to enable them to pose before the world as properly qualified. Under the Medical Acts before a person was recognised as qualified he must prove competency in medicine, surgery, and midwifery, while this Bill proposed to legalise the practice of midwifery by a class of people who were only qualified in one of these branches. If they could be sure that every case would be one of natural labour simple knowledge of midwifery would be adequate, but as in almost every case abnormal symptoms might arise it was necessary that there should be somebody present who was qualified not only in midwifery but also in medicine and surgery. He admitted the worthiness of the motives of those who promoted the Bill, but he denied that its provisions would have the effect desired. It would, in his opinion, largely increase the mortality in connexion with childbirth because it would induce people to employ partially qualified persons to a greater extent than in the past. The Bill, being badly drafted, stood in great need of amendment. Such an amount of amendment was necessary that the work could not be satisfactorily overtaken in the time now at the disposal of the House. In the Bill as it stood there was neither proper local control nor proper means of bringing to book certificated persons who did wrong. The local committee could do nothing but examine and report to the Central Midwives Board, a body sitting in London with no knowledge of the local circumstances, and all the Board could do was to suspend the midwife who did wrong; it had no power to fine her. It might be said that in this matter he was the mouthpiece of certain members of the medical profession who objected to the Bill from motives of self-interest, but this was not the case; he was the mouthpiece of no such people. The medical profession, or at any rate the great majority of the medical profession, objected to the Bill because they considered it contrary to the public interest.

Colonel MILWARD, in seconding the motion, said he objected to the Bill because it was another symptom of the modern craze for examining and registering everybody. They had had a measure for examining and registering plumbers and one for examining and registering architects, and now they had one for examining and registering midwives. Two of the promoters of this Bill were very esteemed country gentlemen, and he supposed that some day they would have a scheme for examining and registering country gentlemen. He was an advocate for greater freedom and a return to the old times when everybody had not to be examined and registered. He was anxious as any man to see the certified midwife properly educated and restricted to her proper duties, but he considered this Bill far too drastic.

Sir JOHN BATTY TUKE then rose to deliver his first speech in the House of Commons. He was received on rising with cheers from all parts of the House. He said that his hope was that this Bill would be allowed to proceed, because he believed it to be an important measure affecting the public health. The mover of the motion used the argument that the conduct of all cases of labour should be relegated to the medical profession. That would be highly desirable, but, unluckily for his argument, midwives had existed from the beginning of the world and he was afraid they would continue to exist. One might as well attempt to suppress the condition which gave her her employment as attempt to suppress the midwife. It had been said that a large number of the medical profession objected to legislation in regard to midwives. That was true. But there was also a large section of the medical profession which approved of the registration of midwives and was anxious that their practice should be regulated. He desired to say that the General Medical Council, of which he had the honour to be a member—a body appointed by Parliament to regulate very important matters in connexion with medicine—approved generally of the Bill now before the House. As the House was aware, a series of Bills on this subject had been introduced. At the invitation of the Lord President of the Privy Council these Bills had been considered by the General Medical Council and after long and serious consideration the latter body had approved of them generally. The Bill now before the House was under consideration at the last meeting of the General Medical Council and its general principles were accepted, if not unanimously, at least by a very large majority. The Council had made suggestions from time to time the influence of which he saw in the Bill now under discussion. In his opinion the Bill contained the essentials of a good measure—registration of midwives, provision for their education, a good midwives board, and a provision by which all those practising midwifery should be under supervision. He must not be understood as approving of all that was in the Bill. He thought it might with advantage be amended very considerably, but he strongly urged the House to allow it to proceed inasmuch as it was an important measure and one which proceeded on the proper lines.

Dr. FARQUHARSON said that he quite admitted the importance of the Bill, but he was not prepared to admit that it had been sufficiently discussed. A large number of medical men opposed it and a large number supported it and with this balance of opinion he thought the House of Commons should be able after due discussion to produce a workable measure. In its present state the Bill was by no means perfect, though he admitted that upon the whole its principle was a good and sound one. He agreed with Sir John Batty Tuke that they could not end the midwife, but if they could not end the midwife they could mend her. At the present moment two-thirds of the poor women of the country in labour were attended by people of their own sex. Some of the midwives were clever, capable women; many of them were stupid, old, and unqualified. All that was wanted was to give midwives some reasonable period of study and some reasonable examination and then to hall-mark them in some reasonable way so as to show that they were qualified for their work. He had put down amendments in the hope of improving the Bill and he felt confident that when the measure came up again for discussion, perhaps in another session, they would be able to make it a really good Bill.

Mr. PARKER SMITH said that his opinion was that this matter should be looked at, not from the point of view of the interests either of medical men or of midwives, but from the point of view of the interests of the women of England and the coming generation, and he felt sure that the medical profession looked at it from this point of view. This was really not a medical man's question at all. The great majority of births were attended not by medical men but by women, and what was wanted by a Bill of this kind was to secure that these women had some kind of qualification. He felt confident that a very small amount of training would be sufficient to get rid of the worst of the dangers now incurred, because a very small amount of training and knowledge would enable these women to discriminate between the cases with which they could deal and the cases which required the skill of the qualified medical practitioner. He hoped the House would not put aside the subject, but express its sense of its urgency and importance by its vote that afternoon.

Sir WALTER FOSTER said he agreed with the last speaker that this was a matter of considerable importance, and because it was a matter of considerable importance he wanted it postponed. He thought he was to some extent responsible for some of this attempted legislation. Seven years ago he endeavoured to move the General Medical Council to take some steps to bring about the better education of women who attended the poor in childbirth and he was still in favour of that principle. For that principle he was prepared at any time to vote, but he was not prepared to vote for a Bill which would abrogate and repeal the Medical Acts of 1858 and 1886 by creating a new class of practitioner which was absolutely unnecessary in the interests of the public. What they wanted was that the public should have in time of childbirth properly educated nurses to look after them and when it was necessary to send for the local practitioner. That was the method by which they treated the paupers in the United Kingdom. The Local Government Board recognised these midwives under certain conditions. They recognised them only on condition that in every case of labour which they attended they let the parochial medical officer know that they

had gone to attend the case, in order to warn him to be in readiness to attend the pauper if any difficulty arose. In that position these women would do a vast amount of good, but put them on this register and they would compete not only with the medical man but with other women engaged in the same business. He thought that all they wanted in the interests of public health, in the interests of the great mass of the people—and it was what the great mass of the medical profession wanted—was that they should have properly qualified women to come in and act as monthly or midwifery nurses in all cases of labour that presented no difficulty and to call in assistance in all cases that did present difficulty. This Bill did not provide that and did not secure it, and because it did not provide or secure that he thought the House should hesitate before it proceeded with it and should give the matter further consideration. Another reason for not proceeding with the Bill now was that there were a large number of amendments standing on the notice paper. Manifestly it was not a Bill which had been properly prepared and properly considered. He was not aware that the Government were prepared to back the Bill in its present form. His own view was that the subject was too large to be dealt with in a private Member's Bill; it ought to be dealt with by the Government in a Bill for which the Government were responsible. He hoped that the Government in another session would take up the matter and give them a Bill they could pass into law.

Mr. HEYWOOD JOHNSTONE, the Member in charge of the Bill, said he quite agreed with Sir Walter Foster that this was a matter which ought to be dealt with by the Government. It ought to be dealt with on the responsibility of the Government of the day. He agreed also with him in hoping that it might in the future be taken up by the Government of the day. But as the Government of the day had not taken it up the promoters of this Bill had felt it their bounden duty to bring the subject before the House and to keep it before the House and before the country. This matter had been the subject of inquiry by select committees of the House in 1892 and 1893.

Half-past five o'clock having now been reached, the SPEAKER made the usual call to order and the debate was thus peremptorily brought to a close. When the debate will be resumed no one can say, for all the time of private Members has been appropriated by the Government for their own business.

PROPOSED EXEMPTION OF HOSPITALS FROM LOCAL RATES.

EVIDENCE BEFORE THE SELECT COMMITTEE.

FRIDAY, JUNE 22ND.

The Select Committee of the House of Commons appointed to inquire into the proposed exemption of hospitals from local rates held another meeting to-day for the examination of witnesses.

Mr. BURT, Chairman of the Central Hospital Board for London, who had been partly examined at the previous sitting, said that the total amount of rates levied upon the 77 scheduled medical hospitals in the metropolis was £21,301 per annum. He thought that this was a burden which institutions of the kind should not be called upon to bear. He considered that a good enough definition of hospitals which should enjoy the proposed exemption would be hospitals carried on, not for profit, but for the care of the sick poor in mind or body and maintained partly or wholly by voluntary contributions or endowments.

In reply to Sir CAMERON GULL, M.P., witness said that the only objection to exemption which had been raised in London came from Lambeth.

The Chairman of the committee (Mr. T. W. RUSSELL, M.P.) said there could be no doubt that if exemption were granted in favour of medical hospitals other institutions would come forward and claim exemption upon practically the same grounds. He had received a letter from an institution in London which gave aid to the sick poor, had no endowments, and depended entirely upon voluntary support, praying to be heard before the committee.

Mr. BURT said he quite admitted that the question presented many practical difficulties, but of course he appeared before the committee to support the claim of the medical hospitals.

Mr. MANDERS of the Irish Office was the next witness and in the course of examination stated that under a series of statutes the hospitals in Ireland were entirely exempt from local rates.

Mr. HOLLAND, Chairman of the London Hospital, Poplar Hospital, and Tilbury Hospital, gave evidence in favour of exemption from local rates. He expressed the opinion that it would be unfair to exclude from the proposed exemption hospitals which happened to have some paying beds. He admitted that if hospitals were exempted other institutions would make a claim for exemption. This was a difficulty, but it was not for him but for that committee to solve it or to suggest a solution. He admitted that it would be reasonable to say that a hospital collecting patients from all parts of England and not doing anything for the parish in which it was situated should not be exempted from the rates of that parish. Perhaps a contribution might be got from the parishes which sent patients to the hospital.

Mr. PATRICK BLAIR, W.S., one of the managers of the Royal Infirmary of Edinburgh, was the next witness. He stated that until the year 1896 the parochial authorities did not demand payment of poor rates and school-rates, or if a notice of assessment was sent in (as occurred once or twice) a simple letter from the treasurer and clerk pointing out that the institution was a charitable one effected the withdrawal of the claim. In the year named, however, intimation was made that the exemption which had hitherto been allowed must cease, in pursuance of the circular issued by the Local Government Board of Scotland on Oct. 28th, 1896. The question of the legality of these particular exemptions had been raised by the official audit, which had been instituted some little time previously and which had enabled the Board to check the procedure of the various local authorities. The matter was remitted to the Law Committee of the Royal Infirmary Board, who reported that as the law stood the institution had no defence against the claim of the parish council, and the rates amounting to £348 15s. 9d. were accordingly paid. In March, 1897, a special committee of the Board, consisting of the then Lord Provost (Sir Andrew McDonald), Professor Rankine, and himself, were appointed to approach the Local Government Board with reference to this question. That committee subsequently met representatives of the Board and discussed the question but without any satisfactory result. In December, 1897, the matter was again before the Law Committee, when they reported that it was their opinion that under the 67th Section of the Poor-law Act, 1845, it would be lawful for the parish council to contribute "annually or otherwise from the funds raised for the relief of the poor" to the funds of the Royal Infirmary the amount of the poor-rate for which the institution was assessed, or such sum as might seem to the council reasonable and expedient. A letter in accordance with this report was therefore forwarded to the parish council, who replied on March 22nd, 1898, that it had been unanimously agreed to refuse the application of the managers for a contribution towards the funds of the institution. The managers of the Royal Infirmary felt most strongly that if there was one institution which, above all others, should be exempt from the payment of poor-rates and school-rates it was that whose affairs they had the honour to control. All treatment and advice at this hospital were granted absolutely free; no letter of recommendation was asked for, the necessity and urgency of the case being the sole requisite qualification. The poor-rates, not only of the city, but of the whole of Scotland were relieved thereby, as by promptly treating free of charge wage-earners who might fall ill or sustain injuries those depending upon them were enabled to do without the parochial assistance which many of them would otherwise require.

In cross-examination Mr. BLAIR said that while the Edinburgh Royal Infirmary had been compelled since 1896 to pay school-rates and poor-rates it had been exempted from the municipal rate.

Mr. HAYES FISHER, M.P., expressed his surprise at this state of things, saying that if the infirmary were to be called upon to pay any rate at all he should have expected it to be the municipal rate.

Mr. JAMES M. DODDS of the Scottish Office laid before the committee a copy of the circular referred to by Mr. Blair which was issued by the Scottish Local Government Board on Oct. 28th, 1896. The circular stated that the exemption of hospitals was not in terms of law unless in cases of inability to pay and intimated that it was the duty of the local boards who were responsible for the recovery of the assessment to see that the owners and occupiers legally liable were duly assessed.

The committee then adjourned.

TUESDAY, JUNE 26TH.

The committee met again to-day, with Mr. T. W. RUSSELL in the chair, and examined five more witnesses.

Sir EDWARD HAMILTON, one of the Secretaries to the Treasury, said that he was strongly opposed to any further extension of the principle of exemption from rates. He thought the principle was thoroughly bad. Anything like an exemption from rates was equivalent to a contribution from rates, and instead of being made in a disguised form it should be made above-board. Instead of exempting them from rates local authorities should, if they thought fit, make a direct grant to hospitals. The policy of the last 30 years had been to include every species of property almost in the valuation list and to draw the net closer and closer. Between 1840 and 1870 there were a good many exemptions made directly by Parliament, but since the later year, with the exception of the exemption accorded to voluntary schools three or four years ago, there had been no case, he thought, of extending exemptions. The concession to the voluntary schools was a substantial one, but he thought he could draw a distinction between voluntary schools and hospitals because one could localise the benefit of the former much better than one could the latter. The children attending a school belonged to the district, whereas the patients in a hospital were usually gathered from other districts. One great objection to providing state aid by means of exemption was that it was impossible that the benefit received should be coterminous with the area taxed. Take such a place as Ventnor, where there was a large hospital for consumptive patients. He understood that it was a large establishment and to omit it from the valuation list would mean a very great loss to the ratepayers of the locality who he imagined, rarely benefited directly from the hospital. He fancied there would be great difficulty in defining the hospital which properly was entitled to relief.

The CHAIRMAN said there was another difficulty which pressed upon his mind. Hospitals were very valuable and did an enormous amount of good work for the poor, but there were other institutions which did precisely the same class of work—orphanages and places of that sort—relieving the poor and doing it from sheer philanthropy and love of human kind. Did the witness think it would be possible to exempt from rates hospitals and not exempt institutions of that kind?

Sir EDWARD HAMILTON said he did not see any standing ground. That was his point; he said that the principle of exemption was bad and that it was impossible almost to draw a line of exemption. He had consulted the Chairman of the Royal Commission on Local Taxation and his lordship (Lord Balfour of Burleigh) had told him he fully contemplated that there would be practical unanimity against the principle of exemption from rating being carried further. The question of hospitals had not been considered by itself by the Royal Commission. He was interested in the Royal College of Music in South Kensington. About five years ago the question was raised whether that institution came within the four corners of the Act of 1843. The question came before the courts and the judge gave his decision in favour of the Royal College, which in consequence was relieved of rates to the extent of £500 or £600 per annum. He did not suppose that the ratepayers of South Kensington were aware that they contributed this amount to the Royal College of Music. He was not opposed by any means to the idea of hospitals receiving aid from the rates, but he thought that the aid should be given in the form of a contribution. He thought that in all cases where the benefit could be fairly well localised the local authority might make a contribution to a hospital, but of course it would be a strong thing for Parliament to say that the contribution should be compulsory.

Mr. RALPH BROCKLEBANK, representing 14 of the hospitals of Liverpool, gave evidence in favour of exemption. The institutions he represented relieved the rates to a very large extent and besides they carried on valuable educational work which, he thought, should be acknowledged. He admitted that it might be difficult to resist other claims for exemption, but he considered the hospitals had a special case, seeing that the patients they treated would have to be otherwise provided for. To relieve the 14 hospitals he represented would mean an addition of one-thirtieth of a penny in the £1 to the rates in Liverpool. When the Liverpool hospitals did not pay rates the ratepayers made no complaint, and he believed if it were legal the Corporation of Liverpool would be willing to forego the rates or, failing that, to make a direct contribution to the hospitals. As for the hospitals, he did not suppose they cared whether the aid came in the form of exemption from rates or of direct contribution.

Mr. WAINWRIGHT, treasurer of St. Thomas's Hospital, who was next

examined, said that last year that institution paid £2566 in rates. If the hospital were relieved of this charge its managers would be able to open two wards with 30 beds each and treat between 380 and 400 in-patients. Owing to want of funds they were obliged to refuse many applications.

Dr. J. M. RHODES said he was the president of the Poor-law Unions' Association of England and Wales, the past president to the Homes for the Feeble-Minded at Birmingham, the chairman of the Chorlton and Manchester Joint Asylums Committee, and a member of the London and also the Manchester Association for Improving the Condition of the Feeble-minded. He believed that the association of which he had the honour to be president was in favour of everything being done to promote the welfare of the feeble-minded who, up to the present time, had been a very neglected class. The only question was this, Could exemption be made in favour of the buildings belonging to this class without an injustice being inflicted in some cases? Take, for instance, a case with which he was well acquainted. An institution for epileptics and feeble-minded was going to be established in another county to that with which he was connected, from which the patients would be drawn. Over 400 acres of land would be occupied, having taken over those buildings and the grounds associated with them. Upon that land between 300 and 400 patients would be placed. Was it right that the authorities in that county should lose the whole of the rates from that institution and have to bear the whole of the expense of maintaining the roads along which all the stores, such as coals, &c., would have to be carted? If they made an exemption in favour of the feeble-minded, where were they going to draw the line? Epileptic colonies and the epileptics, who were certainly as deserving a class as the feeble-minded, would demand, and rightly demand, exemption, and personally he did not see how they were to grant the one and refuse the other. If exemption was given to these institutions it should be on a plan similar to the Agricultural Rating Act, by which the loss to the unions was made good from the Imperial Exchequer. As he said before, the unions had every sympathy with the promotion of establishments for the welfare of the feeble-minded, but they were certainly of opinion that this matter should be dealt with as a whole, not by dealing with it piecemeal, as in this instance, creating a precedent which would no doubt be made a case for exemption of a large number of other institutions which appeared to them equally deserving of exemption.

The Rev. A. W. JEPHSON, the last witness, said he represented the School Board of London who paid £120,000 in rates per annum. The view of the Board was that all exemptions were unfair to the ratepayers who were not exempted. The Board were of opinion that there should be no exemptions and that if possible Parliament should undo the injustice which had already been done. It was an entire misapprehension to say that the Board sent its children to the hospitals in London for the examination of their eyes. They had recommended the parents to have the eyes of their children examined and provided them with a list of the hospitals, but it was a question for the parents where the children should be examined. He might add that the Board no longer gave a list of the hospitals.

The committee then adjourned.

BOOKS, ETC., RECEIVED.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ARMISTEAD, H., M.B., C.M. Edin., has been appointed Medical Officer for the Oswaldtwistle Sanitary District.

ASTIN, W., M.B., C.M. Aberd., has been appointed Medical Officer for the Loughton Sanitary District of the Epping Union, vice F. A. Owgan, resigned.

BARRON, H. T., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Registrar to the Westminster Hospital.

BENNETT, J. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the No. 4 Sanitary District by the Maidstone Board of Guardians, vice A. S. Wood.

BENSON, CHRISTOPHER RICHMOND, M.R.C.S., L.S.A., has been appointed Medical Officer for the Bratton Clovelly District by the Okehampton (Devon) Board of Guardians.

BRAUND, JAMES MONTAGUE, M.R.C.S., L.S.A., has been re-appointed Medical Officer of Health by the Stratton (Cornwall) Rural District Council.

BROWNLEE, J., M.D. Glasg., D.P.H. Camb., has been appointed Physician Superintendent at the Belvidere Hospital by the Glasgow Corporation.

CHESTNUTT, J., L.R.C.P., L.R.C.S., Edin., has been appointed Certifying Surgeon under the Factory Acts for the Howden District.

CLARK, J., M.D. Aberd., F.R.C.S., Edin., has been appointed Certifying Surgeon under the Factory Acts for the Osmotherley District.

CRUICKSHANK, R. W., M.B., C.M. Aberd., has been appointed Certifying Surgeon under the Factory Acts for the Civil Parishes of Cruden and Slains in the county of Aberdeen.

DAVIS, HENRY, J., M.A., M.B. Cantab., M.R.C.P. Lond., has been appointed Assistant Physician to the West London Hospital, Hammersmith-road.

DEY, A., M.B., C.M. Aberd., has been appointed Medical Officer of Health for the Glendale Rural Sanitary District, vice R. Walker, resigned.

FAIRBAIRN, J. S., M.B., B.Ch. Oxon., F.R.C.S. Eng., has been appointed Pathologist to the Chelsea Hospital for Women, Fulham-road London, S.W.

FLANEGAN, H. J., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the Third Sanitary District of the Evesham Union.

FOSTER, PERCY, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Physician to the Sussex County Hospital, Brighton.

FRYER, W. F., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the No. 6 Sanitary District of the Woodbridge Union, vice W. Adams, deceased.

HOLLINSHEAD, F., M.D. St. And., M.R.C.S., has been appointed Visiting Medical Officer at the Infirmary of the King's Norton Union.

HORA, J., M.B., B.S. Lond., L.R.C.P., M.R.C.S., has been appointed Resident Medical Officer at the Infirmary of the King's Norton Union.

KEATING, JAMES, L.R.C.P., L.R.C.S. Edin., has been appointed Certifying Surgeon under the Factory Acts for the Ballygarvan Dispensary District, County Cork.

KELLY, T. J., L.R.C.S. Irel., has been appointed Certifying Surgeon under the Factory Acts for the Enniscorthy Nos. 1 and 2 Dispensary Districts.

LONGFORD, J. M., L.R.C.P., L.R.C.S. Irel., has been appointed Assistant Medical Officer for the Cottage Homes, Aston Union, vice A. Ingram.

MACDONALD, C. R., M.D. Aberd., D.P.H. Camb., has been appointed Medical Officer of the Burgh, Troon.

MCGAURAN, A., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the Newtowngore, County Leitrim, Dispensary District.

MACLENNAN, ALEXANDER, M.B., C.M., L.M. Rotunda, has been appointed Extra Dispensary Surgeon to the Western Infirmary, Glasgow.

MANNIX, J. F., L.R.C.P., L.R.C.S. Irel., has been appointed Certifying Surgeon under the Factory Acts for the Caherciveen District, county Kerry.

MANSON, R. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Northern Sanitary District of the Darlington Union.

MARTIN, FRED. W., M.R.C.S., L.R.C.P. Ed., has been re-appointed Medical Officer of Health to the Borough of Brighouse.

MARTIN, J. M., M.B., B.C. Cantab., D.P.H., has been appointed Medical Officer of Health for the Stroud Rural Sanitary District, vice T. Partridge, resigned.

MITCHELL, ARTHUR M., M.A., M.D., B.C. Camtab., D.P.H. Camb., has been appointed Medical Officer of Health for the Borough of Guildford.

MORGAN, D. N., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer for the Gilfach Sanitary District.

NICHOLSON, T. D., M.B., C.M. Edin., has been appointed Certifying Surgeon under the Factory Acts for the Shap District.

O'DRISCOLL, A. J., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory Acts for the Valencia Dispensary District in Caherciveen Union, County Kerry.

RACE, J. P., L.S.A., has been appointed Assistant Medical Officer for the Gordon-road Workhouse of the Parish of St. Giles, Camberwell, vice F. Friend.

RICHARDS, JOHN, L.R.C.P., Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Conwil Sanitary District by the Carmarthen Board of Guardians.

ROBERTSON, J. A., M.D. Glasg., has been appointed Medical Officer for the Farcet Sanitary District of the Peterborough Union, vice G. S. Payne, deceased.

SIMONS, CHARLES EDWARD GLASCODINE, M.B., C.M. Aberd., D.P.H. R.C.S. Edin., has been appointed Medical Officer of Health for Merthyr Tydvil.

STEDMAN, S. B., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Swinhope Sanitary District of the Caistor Union, vice J. B. O. Richards, resigned.

SUTTER, R. R., M.D. Aberd., L.R.C.P. Lond., M.R.C.S., has been appointed First Assistant Medical Officer for the Poplar and Stepney Sick Asylum.

SWAIN, W. P., F.R.C.S. Eng., has been appointed Honorary Consulting Surgeon to the Devon and Cornwall Ear and Throat Hospital.

SYMONS, WILLIAM HENRY, M.D. Brux., M.R.C.S., L.R.C.P., L.S.A., D.P.H. Oxon. and Durham, has been re-appointed Medical Officer of Health for Bath.

TETLEY, T. WALSH, M.R.C.S., L.R.C.P. Lond., has been appointed Senior House Surgeon to the Clayton Hospital, Wakefield.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BOROUGH ASYLUM, Portsmouth.—Junior Assistant Medical Officer. Salary £120 per annum, rising by three equal increments to £150, with board, lodging, and washing.

BRIDGWATER INFIRMARY.—House Surgeon. Salary £80 per annum with board and residence.

BRISTOL EYE HOSPITAL.—Locum Tenens for the House Surgeon for two months. Salary 2½ guineas a week, without residence.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—House Surgeon. Salary £120 per annum, with rooms and attendance (not board), or £80 per annum, with board.

CARDIFF AND COUNTY PUBLIC HEALTH LABORATORY.—Assistant to the Bacteriologist. Salary £120 a year. Applications to the Clerk of the Joint Committee, Glamorgan County Offices, Cardiff.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road.—Physician to the Out-patient Department.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Resident Medical Officer for twelve months. Salary £60 per annum. Also Registrar. Annual re-appointment, but tenable for three years. Honorarium 20 guineas per annum.

CITY OF LIVERPOOL INFECTIOUS DISEASES HOSPITALS.—Assistant Resident Medical Officer for these hospitals, unmarried. Salary £100 per annum, with board, washing, and lodging at the hospital. Applications to be addressed to the Chairman of the Port Sanitary and Hospitals Committee, under cover to the Town Clerk, Municipal Offices, Liverpool.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY.—Junior House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

CORNWALL COUNTY ASYLUM, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £100, rising to £120 per annum, with board, furnished apartments, &c.

DENBIGHSHIRE INFIRMARY, Denbigh.—House Surgeon for 12 months. Salary £80, with board, residence, and washing.

DEVONSHIRE HOSPITAL, Buxton, Derbyshire.—House Surgeon and Assistant House Surgeon for twelve months. Salary of House Surgeon £100 per annum. Assistant House Surgeon £50, with furnished apartments, board, and washing in both cases.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY, Dumfries.—House Surgeon. Salary £50 per annum, with board and washing.

HAMLET OF MILE END OLD TOWN, London.—Assistant Resident Medical Officer at the Workhouse Infirmary, Bancroft-road, Mile-end, East. Also Assistant Medical Officer to the Workhouse and School, unmarried. Salary £150 per annum, with, board, lodging, and laundry (subject to statutory deduction).—Apply to the Clerk to the Guardians Offices, Bancroft-road, Mile-end, E.

HOLLOWAY SANATORIUM HOSPITAL FOR THE INSANE, Virginia Water, Surrey.—Junior Assistant Medical Officer. Salary £100 per annum, rising £20 annually to £200, with board, lodging, washing, and attendance.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London.—Two House Surgeons to Out-patients, non-resident, for six months. Salary 25 guineas each and lunch at the hospital.

KENSINGTON INFIRMARY.—Resident Assistant, *pro tem.* Salary £3 3*s.* per week, with apartments, board, and washing. Apply to the Medical Superintendent at the Infirmary in the Marloes-road.

KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL. — House Surgeon. Salary £140, rising £10 annually to £170, with rooms in the infirmary and attendance (option of board at £40 per annum).

LIVERPOOL STANLEY HOSPITAL.—Honorary Physician.

LONDON HOSPITAL, Whitechapel, E.—Assistant Surgeon.

METROPOLITAN ASYLUMS BOARD.—Four Assistant Medical Officers—males—at the Fever and Small-pox Hospitals, unmarried. Salary £160 per annum the first year, £180 the second year, and £200 the third and subsequent years, with board, lodging, attendance, and washing (subject to statutory deduction). Applications to the Clerk to the Board.

MIDHURST UNION, Sussex.—Medical Officer and Public Vaccinator for the Tillington District. Salary £60 per annum (subject to statutory deduction). Apply to the Clerk, Midhurst, Sussex.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Medical Officer for six months. Salary at the rate of £60 per annum, with board, attendance, and washing.

NORTH RIDING ASYLUM, Clifton, York.—Junior Assistant Medical Officer. Salary £125, with board, lodging, and washing.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried. Salary £140 per annum, all found except board.

OLDHAM INFIRMARY.—A Senior and a Junior House Surgeon for one year. Salary £85 and £70 per annum respectively, with board, residence, and washing.

PARISH OF BIRMINGHAM WORKHOUSE INFIRMARY.—Assistant Resident Medical Officer for the Workhouse Infirmary, for one year. Salary £100 per annum, with furnished apartments, rations (no alcoholic liquors), coals, gas, laundry, and attendance. Applications to the Clerk to the Guardians, Parish Offices, Edmund-street, Birmingham.

PARISH OF ST. GILES, Camberwell.—Locum Tenens to act for the Medical Officer at the Constance-road Workhouse, East Dulwich, for four weeks. Salary 5 guineas per week, and the usual in-door allowance. Apply to the Clerk to the Guardians, Offices, 29, Peckham-road, S.E.

PONTEFRACT GENERAL DISPENSARY AND INFIRMARY.—Resident Medical Officer, unmarried. Salary £150 per annum, with furnished rooms, fire, lights, and attendance.

POPLAR AND STEPNEY SICK ASYLUM DISTRICT.—Second Assistant Medical Officer for the Sick Asylum at Bromley, Middlesex, E. Salary £100 per annum, with rations, furnished apartments, and washing (subject to statutory deduction). Apply to the Clerk to the Managers, Bromley, Middlesex, E.

ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke-road, Brighton.—House Surgeon for twelve months. Salary £80, and board, lodging, and washing. No stimulants.

ROYAL HALIFAX INFIRMARY.—Senior House Surgeon, unmarried. Salary £90 per annum, with residence, board, and washing. Also Third House Surgeon, unmarried. Salary £50 per annum, with residence, board, and washing.

ROYAL INFIRMARY FOR THE SICK AND LAME POOR OF THE COUNTIES OF NEWCASTLE-UPON-TYNE, NORTHUMBERLAND, AND DURHAM.—Honorary Ophthalmic Surgeon. Applications to the Secretary, Royal Infirmary, Newcastle-upon-Tyne.

RUBERY-HILL ASYLUM FOR THE CITY OF BIRMINGHAM, Barnt green, Worcestershire.—Senior Assistant Medical Officer.

ST. MARY'S CHILDREN'S HOSPITAL, Plaistow, E.—Assistant Resident Medical Officer for six months. Salary at the rate of £60 per annum, with board, residence, laundry, &c.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, London.—Demonstrator of Physiology. Salary £150.

ST. MUNGO'S COLLEGE, GLASGOW, FACULTY OF MEDICINE.—Bellahouston Chair of Anatomy. Emoluments £300 per annum.

ST. PAUL'S HOSPITAL FOR SKIN AND GENITO-URINARY DISEASES, Red Lion-square, London.—Honorary Anæsthetist.

SALOP INFIRMARY, Shrewsbury.—Assistant House Surgeon for six months. Salary at the rate of £60 per annum, with board and washing.

SALFORD ROYAL HOSPITAL.—Honorary Medical Officer for the Pendleton Branch Dispensary.

STAMFORD-HILL AND STOKE NEWINGTON DISPENSARY, 189, High-street, Stoke Newington.—Assistant Resident Medical Officer. Salary £100 per annum, with board.

STAMFORD, RUTLAND, AND GENERAL INFIRMARY, Stamford.—House Surgeon for two years, unmarried. Salary £100 per annum, with board, lodging, and washing.

SURREY DISPENSARY, Southwark, S.E.—Resident Medical Officer. Salary £120 per annum, with furnished apartments, coals, gas, and attendance. Apply to the Secretary, 53, Borough High-street, Southwark.

SUSSEX COUNTY HOSPITAL, Brighton.—Assistant House Surgeon, unmarried. Salary £30 per annum, with board and residence in the hospital.

SWANSEA GENERAL AND EYE HOSPITAL.—House Physician for twelve months. Salary £50 per annum, with board, apartments, washing, and attendance.

THE CHIEF INSPECTOR OF FACTORIES gives notice of vacancies as Certifying Surgeons under the Factory Acts:—At Portsmouth in the county of Southampton; and at Ellesmere, in the county of Salop

UNIVERSITY COLLEGE, Cardiff.—Demonstrator and Assistant Lecturer in Anatomy, and Demonstrator and Assistant Lecturer in Physiology. Salary in each case, £120.

WESTERN GENERAL DISPENSARY, Marylebone-road, London.—Honorary Physician. Also House Surgeon, resident and unmarried. Salary £75 per annum, with board and 10*s.* a month for washing.

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon for one year. Salary £75 per annum, with board, residence, &c.

WEST RIDING ASYLUM, Menston, near Leeds.—Locum Tenens for two months. Salary, three guineas per week, with board and apartments.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon. Salary £100 a year, with board, lodging, and washing. Also Assistant House Surgeon, for six months. Honorarium at the rate of £75 per annum, with board, lodging, and washing.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £110 a year, with board, lodging, and attendance

Births, Marriages, and Deaths.

BIRTHS.

BARENDT.—June 20th, at 65, Rodney-street, Liverpool, the wife of Frank Hugh Barendt, M.D. Lond., F.R.C.S. Eng., of a son.

BUCHANAN.—On June 26th, at Hammersmith-terrace, W., the wife of G. S. Buchanan, M.D., of a daughter.

CROSS.—On June 19th, at The Limes, Wallwood-park, Leytonstone, N.E., the wife of Ernest W. Cross, M.R.C.S., L.R.C.P. Lond., of a son.

FORDE.—On June 18th, at Central-hill, Upper Norwood, S.E., the wife of R. M. Forde, Colonial Surgeon, Gambia, of a son.

GONIN.—On June 19th, at Towcester, the wife of Edmund Henri Gonin, M.D., of a son.

HAMILTON.—On June 23rd, at Sandon-street, Falkner-square, Liverpool, the wife of George G. Hamilton, F.R.C.S., of a daughter.

HORNER.—On June 27th, at St. Mary's-road, Walthamstow, the wife of Charles Julian Horner, L.R.C.P. Lond., M.R.C.S., of a daughter.

LAMBE.—On June 20th, at West View, Seaford, the wife of Thomas Lambe, M.R.C.S., L.R.C.P., of a daughter.

LEWIS.—On June 21st, at Farleigh, Pontypridd, the wife of B. M. Lewis, M.R.C.S., L.R.C.P. Lond., of a daughter.

LISHMAN.—On June 21st, at Puerto Orotava, Teneriffe, the wife of Frederick Lishman, M.D., of a daughter.

MANN.—On June 10th, at Revesby, Lincolnshire, the wife of F. W. S. Mann, M.R.C.S., L.R.C.P. Lond., of a daughter.

PARKINSON.—On June 19th, at Wimpole-street, the wife of J. Porter Parkinson, M.D. Lond., of a son.

ROWE.—On June 20th, at Cecil-street, Margate, the wife of Arthur W. Rowe, M.S., M.B., of a son.

MARRIAGES.

BACON—PLATT.—On the 19th inst., by the Rev. O. P. Sergeant, at St. James's, West End, near Southampton, Robert A. E. Bacon, M.R.C.S. Eng., L.R.C.P. Lond., only son of Robert Bacon, Esq., R.N., of Sandmere, Bitterne Park, Southampton, to Elizabeth S. Platt, second daughter of Charles Platt, Esq., R.N., of Wood Leigh, West End, near Southampton.

CARTER—TOONE.—On June 21st, at Emmanuel Church, Loughborough, Arthur Burnell Carter, M.R.C.S., L.R.C.P., of Dartford, Kent, to Edith Annie, eldest daughter of the late William Henry Toone, Solicitor, of Loughborough.

COURT—PARLBY.—On June 19th, at St. Peter's, South Weald, by the Rev. R. W. Chilton, assisted by the Rev. Canon Fraser, Edward Percy Court, M.R.C.S., L.R.C.P., of Hambledon, Hants, to Lillie, eldest daughter of John P. Parlby, of Harold Wood, Essex.

DUNLOP—GRIMLEY.—On June 22nd, at St. Magnus Episcopal Church, Lerwick, Scotland, Alexander Watson Dunlop, M.A., M.D., Dunrossness, to Agnes, eldest daughter of Mr. William Grimley, Sutton-bridge, Lincolnshire.

HIBBARD—WEST.—On June 27th, at Holy Trinity Church, Cottage-grove, Bow, E., Charles E. Hibbard, L.R.C.P., L.R.C.S., of The Grove, Wandsworth, to Alice, only daughter of James West, Bow-road, E.

MAGUIRE—JEFFERYS.—On June 23rd, at St. Helen's Church, North Kensington, W., George J. Maguire, M.B., Richmond, Surrey, to Louise, younger daughter of Francis Jefferys, of Cambridge-gardens, W.

RUST—SHIERS.—On 21st inst., at St. Margaret's Church, Dunham Massey, by the Rev. Albert Rust, brother to the bridegroom, assisted by the Ven. Archdeacon Woosnam, John Rust, M.R.C.S., L.R.C.P., of 30, St. Mary's-road, Crumpsall, Manchester, third son of John Rust, Ditchingham, Norfolk, to Florence Louisa, youngest daughter of the late Richard Shiers of Bowdon, Cheshire.

VASEY—GRIFFITHS.—On June 21st, by the Rev. W. Hardy Harwood, at Union Chapel, Islington, S. Arch. Vasey, F.I.C., F.C.S., of Loughton, Essex, to Gertrude, the youngest daughter of J. J. Griffiths, Esq., J.P., of Highbury-grange, N.

WYLLYS—BALLANCE.—On June 21st, at St. George's, Hanover-square, Henry John Mackeson Wyllys, F.R.C.S.E., of Great Yarmouth, to Rosa Louisa, third daughter of the late Charles Ballance of Clapton.

DEATHS.

FARR WHITE.—On June 20th, at Leopold-road, Wimbledon, George Farr White, F.R.C.S., late Assistant Surgeon, H.M.'s 77th Regiment.

FITZ HUGH.—On June 15th, at the Imperial Hospital, Deelfontein, Civil Surgeon Richard Truman Fitz Hugh, M.B. Lond., aged 28 years.

FORRESTER.—On June 19th, at Cape Town, Surgeon-Lieutenant-Colonel J. S. Forrester, Royal Horse Guards, aged 46 years.

HOPE.—On June 21st, at Church-hill, Petworth, Samuel Wilson Hope, M.R.C.S., L.R.C.P., in his 56th year.

JONES.—On June 20th, at Windsor Esplanade, Cardiff, Francis William Brandram Jones, M.D. Edin., aged 39 years.

RAMSDEN.—On 24th inst., suddenly, at Sunnyside, Dobcross, Saddleworth, Walter Henry Fox Ramsden, M.R.C.S., L.R.C.P., aged 66 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A LAYMAN'S VIEWS OF INEBRIETY.

A CORRESPONDENT writes:—So great an interest has been aroused in the arguments for and against the so-called temperance question at the present time that the following translation of a quaint passage from the writings of Pufendorf can scarcely fail to be of interest. The translation was made by Mr. R. Milne, who sent it to the Society for the Study of Inebriety. That society caused it to published in their pamphlet of Proceedings. Many of the temperance journals have unwarrantably assumed that the society is necessarily an ardent patron of teetotalism. Most of the so-called temperance reformers aim not at temperance or moderation in drinking, but at total abstinence. The society mentioned, however, does not consist and is not intended to consist of teetotal members. It exists for the study of inebriety as such and not for its extinction or suppression. Thus, as a really learned body the society does not hesitate to hear and discuss all sides of a question. One may feel sure that such breadth of view in investigation can only result in the attainment of really valuable knowledge of the subject. One cannot feel much confidence in the conclusions arrived at about inebriety or excess in drinking by societies known to be prejudiced in favour of total abstinence and intolerant of the views of the millions of moderate drinkers. The passage is as follows:—

We should ask *why* people get drunk? And *how* it is that some keep sober?"

One is sober because he has not the means to get drunk.

Another because greater pleasures than drunkenness are within his reach.

Another simply through *fear*, whether of the law, or of his fellows.

Another because drunkenness hinders his pursuits and the ends he has most at heart. Thus are great criminals sober.

[This last observation is of great antiquity. Aristotle wrote: "If the knave be sober through design, and the invalid through necessity, the wise man will be so from choice and the good man from a sense of duty."]

One is drunk simply because his bodily machine is so crazy and dilapidated that he can find no other way to keep his brain alive but through drunkenness.

Another because of the desolation and the joylessness of his life. He drinks to forget.

Another because drinking exalts certain powers of his body or mind for a time.

Another because drinking feeds the vices he takes most pleasure in.

Another because drinking makes him feel big and important.

Another is drunk because drinking eases certain stomach distresses.

Another because the *very ideals* of the sober party are hateful to him.

Another simply because he has somehow got into the habit of drinking.

Another to stave off exhaustion.

Another because his dietary is unsuitable to him.

Saint and sinner alike we all seek pleasure, and men will go wherever to their understandings the greatest promise of pleasure is held out. All these notions, both of sober and inebriate, are at root one and the same, the getting of pleasure or the avoidance of pain of every degree whatsoever, for if you can avoid pain you will be absolutely happy. And this absolute easing it is that gives the "beatific vision" to the face of the dead. There is no more tension. While we live there must be this tension, for only thus is life, work possible. And this tension means myriads of tiny worries and distresses, most of them through habit unknown even to ourselves.

What, then, are the remedies?

In one word, Knowledge. All else will follow. We must *take counsel with* the inebriate. And before he will allow that he must see that you love him, that you respect him, and you understand him and his bodily and mental needs. There is no reformation, no amendment, but *from within outwards*. You must coöperate with the man himself.

The translator adds: "There seems to be in this book the ancient, the eternal, confusion between what a man ought to do and what his neighbours have a right to require of him. By 'ought to do' I mean either what is due to his Maker or what is due, fitting, becoming to himself. Do you really think you have the *right* to compel your neighbour to be sober, supposing you had the power? I mean no offence in thus asking."

PULEX IRRITANS.

C. M. H. wishes to know how to get rid of a plague of fleas in an old country house where the pests have established themselves in the woodwork and cracks of the floors. In THE LANCET of April 6th, 1895, p. 882, and in our issue of May 14th, 1898, p. 1344, the subject is dealt with, but perhaps some of our readers may be able to help our correspondent further. The use of formalin, of which we have no experience in this particular application, is suggested, but if it is tried we would recommend as an additional measure that a stiff soapy lather should be worked into the cracks and crevices of the boards before or after fumigation and allowed to remain for 24 hours.

HOMES FOR INCURABLE POOR.

To the Editors of THE LANCET.

SIRS,—Could any of your readers kindly give me the addresses of homes for incurable patients, where the patients are received for very nominal amounts per annum?

I am, Sirs, yours faithfully,

Hayle, Cornwall, June 25th, 1900. H. ROBERTS.

"DEATHS UNDER CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—In the issue of THE LANCET of June 23rd, 1900, p. 1846, appears a letter from Mr. C. J. Harris, in which he quotes the case I reported in your issue of June 9th, 1900, using that case to draw a comparison between the older method of giving chloroform and the latest fad of the Krohne Inhaler. But Mr. Harris does not quote correctly. He says that chloroform in my case "was administered by the towel or Simpson's method." Well, it was not so. The chloroform was given on an inhaler of the Skinner type to the patient on both occasions and on both was the same amount used. Giving chloroform as I am doing very frequently I can practically be certain that I hold the mask the same distance from the face in every case, so that the concentration of the vapour of chloroform and air is the same in each case, and according to experiments by S. J. Lister the percentage of chloroform is about 4·5 per cent., and I maintain that an ounce of chloroform used on an open inhaler during the space of 20 minutes, of which the patient gets 4·5 per cent., cannot be in any way construed as an excessive dose; my patient certainly had quite as much chloroform on the second occasion with no ill results. I cannot explain why he behaved as he did on the first occasion, but in view of the second operation I state emphatically that it was not an overdose, and I am certain that had the chloroform been given in a Krohne or any other inhaler the result would have been the same. The advocates of some particular new fad are always quoting any case under the old conditions, but one notices that no figures are given in support of the new *régime*, and when one considers the huge number of occasions on which chloroform is given under what they are pleased to term the "old" method in a year and the comparatively insignificant number of casualties resulting, one feels inclined to go on until one's own figures at any rate are equalled. I have administered chloroform up to date 576 times with no deaths and I know two of my fellow anæsthetists, one of whom has had over 3000 cases with no deaths and the other over 1500 cases with no deaths. When I see these figures equalled under any new conditions it will be then quite time enough to change from the "old" to the new.

I am, Sirs, yours faithfully,

FRANK E. MARSHALL, M.B., Ch.B. Vict., L.S.A.,
Anæsthetist to the Royal Southern Hospital, Liverpool.

Liverpool, June 22nd, 1900.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of June 16th, 1900, there is a very interesting paper upon anæsthetics by Dr. Dudley Buxton. But there is one sentence on which I think we need further light. Dr. Buxton writes (page 1715, col. 2):—

> "It is one great advantage of inhalers such as Junker's over the open method that you can give chloroform in great dilution but maintain the continuity of the inhalation. With skill and judgment the drop-bottle method with a Schimmelbusch's mask will give a good result, but it is inferior to a regulating inhaler."
>
> At page 1716, col. 1, Dr. Buxton again writes: "..... I gave him oxygen with chloroform with the best result. I administered oxygen continuously and exhibited chloroform from my modified form of Junker's inhaler."

Many readers will be thankful to see this pronouncement, and especially the essential principle of "great dilution," "extreme dilution and slowly." But what instrument does Dr. Buxton mean by "the Junker inhaler"; what by "a regulating inhaler"; and what by "my modified form of Junker's inhaler"?

This is a serious question because practitioners who order "a Junker inhaler" or "a Buxton's modified Junker" will have planted upon them an obsolete and dangerous instrument which can hardly be what Dr. Buxton means. Of course, "with skill and judgment," if only there be enough of it, the drop method on the flannel mask, the towel method, an old Junker, *or any other method* may be made safe. But the drops of chloroform that come off the lip of a bottle vary in size with the shape, magnitude, and thickness of the lip. Moreover, the saturated flannel mask does not enable one to measure the volume of chloroform-air which goes into each inspiration. In fact, it is a rule-of-thumb method and the graduated drop-bottle is illusory.

As to the "Junker inhaler" it has two fatal faults. The respiration orifice, when the throttle valve is fully open, is of smaller cross-section than the glottis and is inadequate to save from asphyxiation. Moreover, it cannot be seen whether this throttle valve on the collar of the

inhaler is open or shut except by the administrator on his stooping down to make a close inspection. This is a very dangerous fault and it adds the risks of asphyxiation to the chances of chloroform poisoning. The old Junker is, however, safer than the Junker modified by the rubber-inflator, which makes the mask air-tight to the face. With the old Junker the throttle valve was useless and unsafe, but the patients' lives were saved by the fact that the periphery of the facepiece, being of rigid vulcanite, never fitted the face air-tight. Large chinks remained open between the patient's face and the base of the mask, and while the administrator was worrying over the illusory throttle valve the patient was breathing comfortably through these chinks. These chinks also made it extremely difficult for the most strenuous pumper to kill his patient, inasmuch as the heavy chloroform vapour drained out through the chinks at every expiration. But when the rubber inflator was put on to the edge of the mask it fitted the face air-tight and the improved Junker became a death-trap.

The presence of Krohne's two fire-engine balls so as to produce a continuous jet of chloroform-air all round the respiration cycle also made the apparatus chaotic in action and practically unmanageable. The result was that practical men preferred the towel method, or any other, and they were then quite right.

Subsequently to the application of the rubber inflator Krohne knocked off altogether the collar and its valve and replaced them by a large respiration orifice many times the area of the glottis and always open—unless some sage stops it up with a towel or puts his hand over it. Krohne thus transformed the inhaler. It was now perfect except as to one point—the survival of the continuous jet. It was my good fortune to point this out in THE LANCET of Oct. 28th, 1899, pages 1205–6. Krohne at once adopted the single ball and improved valve as suggested by me. The result now is an inhaler with which any volume of chloroform-air can be injected into each inspiration, and *if worked as described by me* the whole of the chloroform used goes into the recesses of the lungs. All that is now necessary is for the administrator to learn to think of his chloroform in fractions of a minim instead of in fractions of an ounce. Krohne added the "feather indicator," which exhibits to everyone in the room the rhythm and amplitude of every phase of each respiration cycle.

What I desire to point out is that if we want the right implement we must order the "Krohne Inhaler 1900." In this we have the fundamental step made by Junker of pumping chloroform vapour into a facepiece, the continuous jet abolished, the rubber inflator to close up the chinks round the periphery of the mask, the large uncloseable respiration orifice, and the feather indicator. It is a perfect instrument. But it will not be obtained under either of the names used by Dr. Buxton.

One more point. It is useless to talk vaguely and incidentally of "large dilution" of the chloroform vapour. What is large dilution? Sound teaching should point out that the anæsthetising atmosphere must contain from 1 to 2 per cent., by volume, of chloroform vapour; that a larger percentage is dangerous and is only to be used on rare occasions. 1 to 2 per cent. means one to two cubic inches of chloroform vapour diluted up to a volume of 100 cubic inches with pure fresh atmospheric air. Such an atmosphere, continuously inspired, induces a safe, comfortable, and perfect surgical anæsthesia, in less than ten minutes, and with a total abstraction from the graduated burette of from 30 to 50 minims of chloroform. And the anæsthesia is as pleasant as the 40 winks into which a tired man drifts in an afternoon siesta. The first ten inspirations should carry into the lungs even less than 1 per cent. of chloroform vapour. First, we gently benumb the reflex irritability of the larynx and air-passages. That having been achieved we commence the work of charging up the whole mass of the circulating blood and its extra-vascular plasma. This charging up of the system requires time for the necessary diffusion and penetration. It must be so graduated that a killing surcharge is never at any moment precipitated into those few cubic inches of blood which lie between the capillaries of the pulmonary artery and the capillaries of the coronary arteries—a fraction of the circulation which I have described as "the pulmo-cardiac blood," and on which the life of the heart depends. A momentary surcharge here kills the heart.

I am, Sirs, yours faithfully,

Manchester-square, W., June 23rd, 1900. JAMES EDMUNDS.

"THE YOUNG PRACTITIONER, HIS CODE AND TARIFF."

To the Editors of THE LANCET.

SIRS,—Will someone inform me in the columns of THE LANCET where I can obtain a copy of this work? I can gain no information about it at the usual shops.

I am, Sirs, yours faithfully,

June 17th, 1900. M.R.C.S., L.R.C.P.

POINTS IN ETIQUETTE.

C. G. D. asks:—

1. What course should be adopted when a junior partner in a large general practice refuses to be governed by the ordinary rules of etiquette in his conduct to his partner and totally ignores all rules by which medical men are usually governed? 2. Also, can a junior partner in a large general practice accept an honorary appointment in a hospital (which may take him away from his work probably for some hours each day) without the consent of his partner?

1. The gist of the first question lies in the words "ordinary" and "usually." No member of the profession, we are sure, would willingly infringe the rules of medical etiquette, whether he did so to the detriment of his own partner or of any other medical man, but the rules are not as definite in many directions as they might be and presumably the junior partner differs from his senior in his interpretation of them. 2. The answer to the second question depends upon the phraseology as well as upon the meaning of the agreement between the partners. It may be good for the practice that one or the other partner should hold an appointment in a hospital, and the junior partner might be able to bring evidence that such is his view. In general answer to both questions we would say that it is perfectly clear that the matters in dispute should be settled amicably by arbitration. A medical man of senior standing whose position is recognised as a good one by both partners should be asked to decide upon the *modus vivendi*.

O. H. B.—No book contains the information in question. The position of the General Medical Council now practically is that the employment of unqualified assistants is completely forbidden. A practitioner may be accompanied to a case by a *bonâ-fide* pupil, while the chief difference between a pupil and an assistant lies in the fact that the former pays for information that he is gaining, whilst the latter is paid for help that he is rendering. We cannot reply more definitely than this.

B. O.—In our opinion the Oxford graduate should be considered the senior man, but we can only give an opinion. If the matter is of importance the electing body should decide which is to be considered senior.

Ethics.—We regret to be unable to help our correspondent, but have published his letter as some of our readers may be better informed than we are.

A Subscriber.—The possession of such diplomas would make their owner "doubly qualified."

ERRATA.—In the letter of Dr. Chaumier, headed "A Propos du Rapport de la Commission de THE LANCET, sur la Pulpe 'Vaccinale' Glycérinée," which appeared in our issue of June 23rd, p. 1831, the following corrections should be made: On page 1832, col. 1, line 7, Chalybaüs should read *Chalybäus*; on page 1833, col. 1, line 18, the word printed "infinie" should be *infime;* in paragraph 2, line 2 "pouvait" should be *pourrait*; paragraph 4, lines 4 and 5, "Grigorien" and "Volton" should read *Grigoriew* and *Voitow*.—In THE LANCET of June 2nd, on page 1629, column two, paragraph two, lines 10 and 11 should read: "It had taken place since he ceased to be a member of the board—i.e., February, 1897."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Western Mail, Western Morning News, Whitehall Review (London), South Wales Daily News, Sydney Daily Telegraph, Leeds Mercury, Staffordshire Sentinel, Macclesfield Courier, Dewsbury Reporter, Manchester Guardian, Newcastle Daily Chronicle, Birkenhead News, Daily Mail (London), Gazette (Middlesbrough), Norfolk Daily Standard, Times of India, Pioneer Mail, Architect, Builder, Citizen, Bristol Mercury, Yorkshire Post, Caterer, Liverpool Daily Post, Sanitary Record, Barrow Herald, Siam Free Press, Brighton Gazette, Jersey Express, Carmarthen Reporter, The New Age, Drogheda Advertiser, Morning Post, Morning Advertiser, Warrington Guardian, Christian World, City Press, Reading Mercury, Local Government Journal, Natal Mercury, Surrey Advertiser, Swansea Journal, Manchester Evening Chronicle, Mining Journal, Local Government Chronicle, Hertfordshire Mercury, Preston Herald, Torquay Times, Topical Times, Hastings Times, Lincoln Mercury, Horse Guards Gazette, Chelsea Mail, Public Health Engineer, The Observer, Chester Guardian, Walsall Observer, Daily Express (Dublin), South London Press, Liverpool Journal of Commerce, Scotsman, &c., &c.*

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.).

WEDNESDAY (4th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.)

THURSDAY (5th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.).

FRIDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Lonpon Throat (2 P.M. and 6 P.M.).

SATURDAY (7th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

SATURDAY (30th).—PATHOLOGICAL SOCIETY OF LONDON (Pathological Laboratory, New Museums, Cambridge).—4 P.M. Papers and Demonstrations by Prof. Woodhead, Dr. Dixon, Dr. Eyre, Mr. Griffiths, Dr. Nuttall, Dr. Cobbett and others. 6.30 P.M. Dinner in Trinity Hall.

WEDNESDAY (4th).—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. H. Roberts, Dr. Blacker, and Dr. Fairbairn. Paper:—Dr. A. Routh: Porro-Cæsarean Hysterectomy with Retro-peritoneal Treatment of the Stump in a Case of Fibroids obstructing Labour, with Remarks upon the Relative Advantages of the modern Porro Operation over the Sanger-Cæsarean in most other cases requiring Abdominal Section.

FRIDAY (6th).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 P.M. Cases and Card Specimens. 8.30 P.M. Papers:—Mr. F. M. Ogilvie: On one of the Results of Concussion Injuries of the Eye ("Holes" at the Macula).—Mr. K. Scott and Mr. J. Griffith: Alveolar Carcinoma of Eyelid.—Mr. C. D. Marshall: Further Notes on a Case of Optic Nerve Tumour previously reported to the Society.—Mr. P. Flemming: Three Cases of Ophthalmitis ("pseudoglioma") in Children, One Recovery, Two Fatal, from Meningitis. The Annual General Meeting will be held after the Ordinary Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (2nd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. Galloway: Consultation. (Skin.)

LONDON THROAT HOSPITAL (204, Gt. Portland-street, W.).—4.30 P.M. Mr. C. Woakes: Demonstration on Selected Cases. (Post-graduate Course.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Keetley: The Diagnosis of, and Operations for, Diseases of the Breast.

TUESDAY (3rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. F. Payne: Consultation. (Medical.)

BRUSSELS MEDICAL GRADUATES' ASSOCIATION (Café Royal, Regent-street, W.).—6.30 P.M. Twentieth Annual General Meeting. 7.30 P.M. Dinner.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, W.C.)—3.30 P.M. Mr. M. Gunn: Ocular Paralysis.

WEDNESDAY (4th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—8.30 P.M. Formal Opening of New Clinical Museum by Sir William Broadbent. 9 P.M. Clinical Lecture:—Prof. Osler: The Teaching of Practical Medicine.

EVELINA HOSPITAL (Southwark-bridge-road, S.E.).—4.30 P.M. Dr. W. S. Fenwick: On Diarrhœa in Children. (Post-graduate Course.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Schorstein: The Forms of Dyspepsia in Pulmonary Tuberculosis.

MASON UNIVERSITY COLLEGE, BIRMINGHAM (Medical Lecture Theatre of the College).—4 P.M. Dr. O. J. Kauffmann: The Commoner Neuroses of Childhood, their Pathology and Treatment. (Ingleby Lecture.)

THURSDAY (5th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Keetley: The Diagnosis of, and Operations for, Diseases of the Breast.

CHARING-CROSS HOSPITAL.—4 P.M. Dr. M. Davidson: Röntgen Ray Demonstration. (Post-graduate Course.)

FRIDAY (6th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. Tilley: Consultation. (Nose and Throat.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1900, which is completed with the issue of to-day, will be given in the next number of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1900 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

Communications, Letters, &c., have been received from—

A.—Miss A. S. Althaus, Lond.; Messrs. Armour and Co., Lond.; Messrs. Allen and Hanburys, Lond.; Apollinaris Co., Lond.

B.—Mr. R. Beauchamp, Lond.; Mr. W. Bernard, Londonderry; T. B. Browne, Ltd., Lond.; Mrs. E. M. Berragry, Lond.; British Antitoxine Co., Lond.; Messrs. Burroughs Wellcome and Co., Lond.; Dr. Boehm, Berlin; Professor Boyce, Liverpool; Mr. L. Browne, Lond.; Messrs. Boulton and Paul, Norwich; Messrs. C. Barker and Son, Lond; Mr. J. C. Briscoe, Lond.; Dr. A. G. Bateman, Lond.; Dr. Charles Burland, Lond.; Dr. T. B. Broadway.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Croonian Lectures

ON

THE DEGENERATION OF THE NEURONE.

Delivered before the Royal College of Physicians of London on June 19th, 21st, 26th, and 28th, 1900,

BY FREDERICK W. MOTT, M.D. LOND., F.R.S.,

PATHOLOGIST TO THE LONDON COUNTY ASYLUMS; PHYSICIAN-IN-CHARGE OF OUT-PATIENTS, CHARING-CROSS HOSPITAL.

LECTURE III.[1]

Delivered on June 26th, 1900.

THE CHEMISTRY OF DEGENERATION AND ITS RELATION TO AUTO-INTOXICATION.

MR. PRESIDENT AND GENTLEMEN,—Osmic acid has long been known to have the property of staining fat (including myelin) black, but owing to difficulty in penetration it could not be made use of for studying the degeneration of the central nervous system in the same way as the peripheral, although Exner[2] was enabled to show by this method the existence of fine medullated fibres (tangential system and supra-radial) in the grey matter of the cerebral cortex, and Tuczek applied this method and demonstrated the important fact that atrophy of the tangential fibres of the frontal and central convolutions was the earliest and most constant morbid change in dementia paralytica. I have had the opportunity of confirming this observation in at least 50 cases by the Marchi-Pal method. This degeneration does not appear to be peculiar to general paralysis, as similar atrophy may occur in other diseases of the cerebrum associated with dementia, as, for example, in alcoholic and epileptic dementia; it does not, however, exist in purely efferent systemic degeneration—e.g., amyotrophic lateral sclerosis—although in this disease, as I shall show, the whole motor efferent system of neurones from cortex to peripheral muscle is degenerated.

THE VALUE OF THE MARCHI METHOD.

About ten years ago Marchi introduced his method of staining degenerated nerve fibres, using it for the purpose of demonstrating the degenerations which followed experimental ablations of the cerebellum performed by Luciani, and the most striking results were obtained. By this method Marchi showed a descending cerebellar system in the antero-lateral column of the same side as the half of the cerebellum that had been removed. Russell, Ferrier, and Turner have, however, shown that this tract does not proceed direct from the cerebellum but through a relay in Deiter's nucleus. It is now the method adopted by all investigators for determining the path, not only of tracts of fibres, but of actual individual fibres, in the central nervous system. It has, in the hands of numerous investigators, served to demonstrate accurately the course and termination of nervous paths. There are a few fallacies in connexion with it for the inexperienced, but if care be taken to avoid these no method is so delicate or so reliable. By this method I was able to trace the course of the fibres of Gowers's tract, which I showed to consist of three sets of fibres; one, the more numerous, terminating in the middle lobe of the cerebellum after looping over the fifth nerve and running down on the surface of the superior cerebellar peduncle; another set terminating in the corpora quadrigemina; and the third, few in number, joining with the fillet fibres and ending in the optic thalamus. By this method single fibres can be followed in their course along the whole cerebro-spinal axis, from the cortex to the lumbar sacral region when they are efferent, and from the lumbar sacral region to the optic thalamus when they are afferent. I was unable to find any evidence for the existence of a cortical fillet described by Flechsig after cutting off the posterior column nuclei in monkeys and tracing the degeneration upwards, all the fillet fibres terminating in the optic thalamus.

THE CHEMISTRY OF THE MARCHI METHOD IN RELATION TO DEGENERATION.

In working with the Marchi method I was struck by the fact that in the neighbourhood of a lesion vessels could often be seen with phagocytes containing black-stained particles in their sheaths. These were undoubtedly carrying away the products of degeneration. I also found that muscles which had undergone fatty degeneration reacted to the Marchi stain—that is to say, pieces of muscle which had been hardened in Müller's fluid, like pieces of the degenerated central nervous system, when placed in the Marchi fluid for from 10 to 14 days (one part of 1 per cent. of osmic acid and two parts of Müller's fluid), revealed fatty degeneration by the fat particles being stained black. I had long before noticed that the fat particles in degenerated muscle were stained by the hæmotoxylon when the Weigert or Weigert-Pal method of colouration was used; therefore, I came to the conclusion that a non-phosphoretted fat, the result of degeneration of proteid, would be stained by either of these methods. Putting this fact by the side of another—viz., that degenerating nerves of the central nervous system stained by the Weigert or Weigert-Pal method appear uniformly blue throughout, whereas in a transection of the normal nerve-fibres only a ring of myelin stains blue, the central axon being unstained—the conclusion is that the proteid of the axon has degenerated and become converted into a fatty substance; but it is otherwise, as I shall now show, with the Marchi method, which really depends for the success of the reaction on the differential staining of the phosphoretted fat contained in the myelin (protagon) from ordinary (non-phosphoretted), such as olein, palmitin, stearin, &c. In sections of a normal nervous tissue stained by the Marchi method the nerve-fibres in transection present the following appearances: the central axial core is unstained, the ring of myelin is stained a greenish ash-grey colour, and degenerated fibres are stained black throughout, so that no differentiation can be seen between the myelin sheath and the axial core. It might be said that this was due to the axial core having broken up and its place being occupied by the degenerated myelin, but I have observed in longitudinal sections of nervous tissue showing degeneration in the earliest stages the axis-cylinder stained black, as well as the myelin (Fig. 1).
